[d] Small mines include Jefferson County. No production in Keokuk County.

KANSAS.

A large increase in production of coal in Crawford County and a small increase in Osage County, which together offset decreases in all other counties, gave the Kansas coal fields an increase of 376,972 tons, or 5.2 per cent, in 1918 over 1917. The production in 1918 was 7,561,947 tons, and was the highest recorded for the State, the nearest approach to this figure having been in 1907, when the production was 7,322,000 tons. The increase in production was attained with approximately the same number of men employed, but working a greater number of days, 234 men in 1918 against 216 in 1917.

The weekly reports of operating conditions in Iowa, Missouri, Kansas, Oklahoma, Arkansas, and Texas, comprising what was described as zone 17 by the Fuel Administration, are combined and

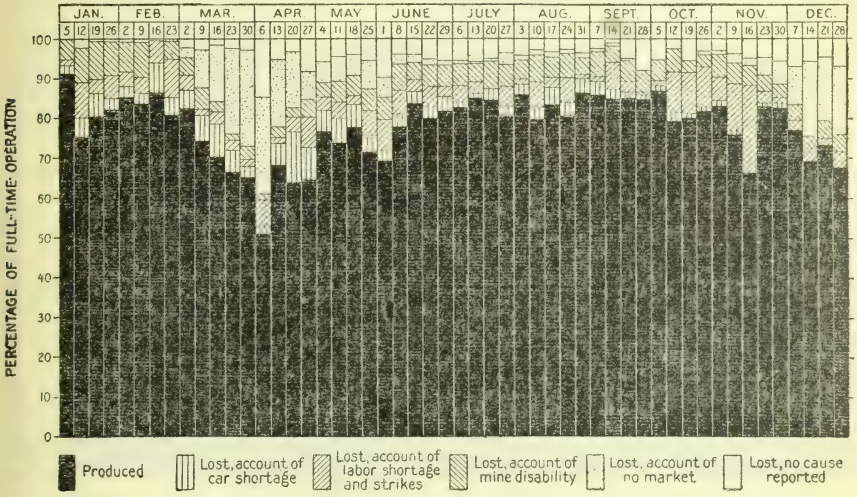

FIGURE 79.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in Iowa, Missouri, Kansas, Oklahoma, Arkansas, and Texas, in 1918.

shown graphically in figure 79. In this general field the strength of the market was the factor of greatest importance in determining the rate of production. At no time in 1918 was loss of operating time because of car shortage as great as in the eastern fields.

Coal produced in Kansas in 1917.

KENTUCKY.

The production of coal in Kentucky in 1918 was 31,612,617 tons, valued at $80,666,842, an increase compared with 1917 of 3,804,646 tons, or 13.7 per cent, in quantity and $20,369,189, or 33.8 per cent, in value. Both eastern and western Kentucky shared in this increase. The production in the eastern part of the State was 20,723,023 tons, valued at $56,179,991, in 1918, a gain compared with 1917 of 3,219,475 tons, or 18.3 per cent, in quantity and $12,793,001, or 29.5 per cent, in value; and the production in the western part of the State was 10,798,690 tons, valued at $24,274,312, an increase over 1917 of 584,210 tons, or 6 per cent, in quantity and $7,536,913, or 45 per cent, in value. It will be recalled that in 1917 the western part of the State recorded much the larger gain over 1916, and it is interesting to note that the production in eastern Kentucky

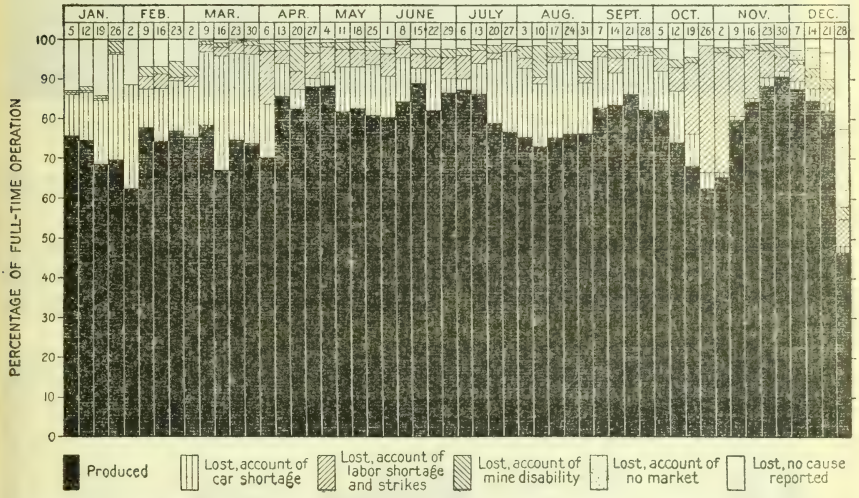

FIGURE 80.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in southeastern Kentucky and in Tennessee, in 1918.

in 1918 represented a gain of 18.4 per cent and the production in the western fields a gain of 39 per cent, as compared with 1916.

The increases in 1918 were more or less general, the only counties to record decreases, and those slight, were Johnson, Letcher, and Morgan in the east and Hopkins in the west.

The weekly reports of operating conditions shown graphically in figures 80, 81, and 82 indicate the lowest average percentage of full-time operation in western Kentucky, with car and labor shortage as the principal factors limiting production. In the Hazard and northeastern districts car shortage was largely responsible for nonproduction in the first half of the year, and in October and November labor shortage, resulting from the epidemic of influenza, was the important cause of closing down the mines. The weekly statistics for southeastern Kentucky are combined with Tennessee and shown in figure 80. In this region conditions of car supply and labor were generally better than in the western and northeastern parts of the State.

In all districts lack of demand or "no market" was a noticeable feature during the last few weeks of 1918.

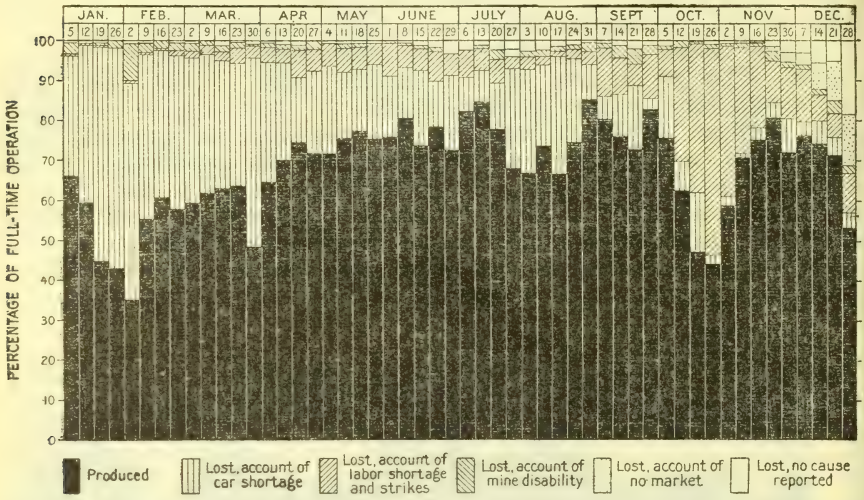

FIGURE 81.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in the Hazard and northeastern districts of Kentucky, in 1918.

The average number of days worked increased from 214 in 1917 to 230 in 1918—from 209 to 231 in the eastern districts and from 225 to 228 in the western districts. Likewise there was an increase in

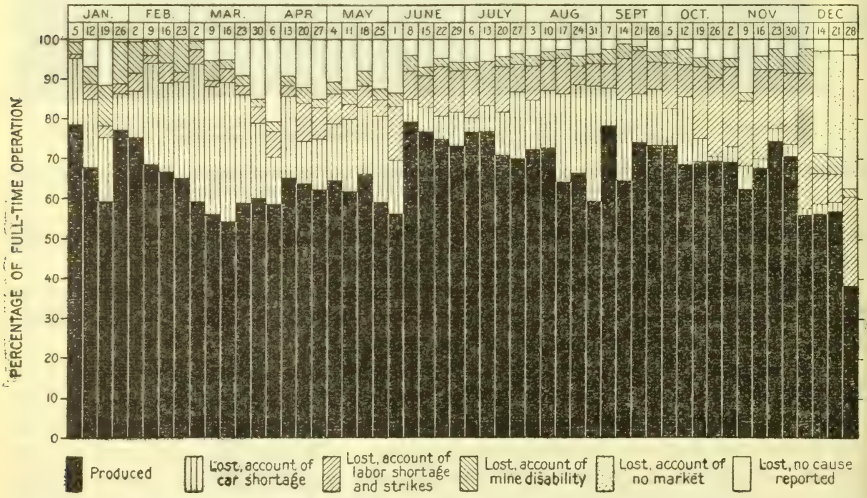

FIGURE 82.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in western Kentucky, in 1918.

the number of men employed in both fields—the number in the eastern part of the State increased from 23,503 in 1917 to 26,918 in 1918 and the number in the western field increased from 11,423 to 12,424.

b Hancock County included in small mines.

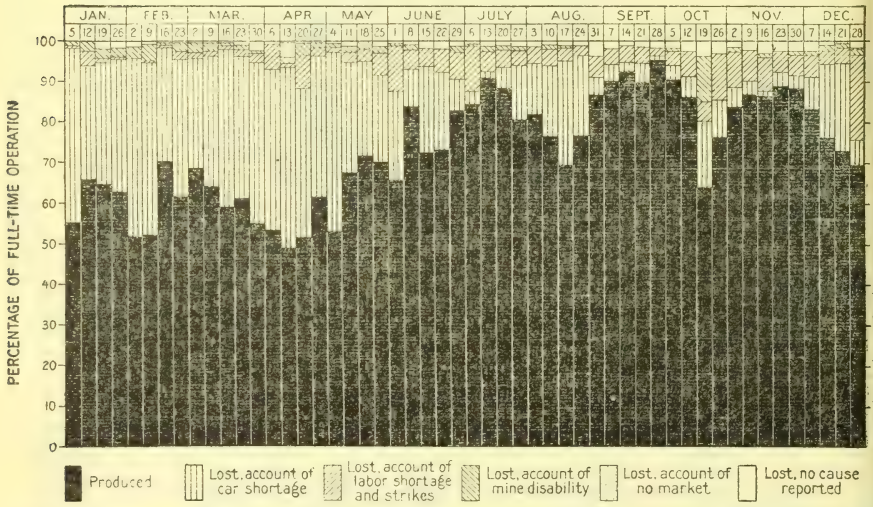

FIGURE 83.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in the Cumberland-Piedmont district, Md.-W. Va., and the Somerset district, Pa., in 1918.

MARYLAND.

The production of coal in Maryland in 1918 was 4,497,297 net tons, valued at $12,466,189, a decrease, compared with 1917, of 248,627 tons, or 5.2 per cent, in quantity but an increase of $798,337, or 6.8 per cent, in value. As compared with 1917 the average number of days worked increased slightly, from 254 to 261, and the number of men employed decreased from 5,919 in 1917 to 5,568 in 1918; the decrease in output is to be attributed to a comparative shortage of labor. With the labor that was available, however, more coal could have been produced had the mines been able to operate more days in the year. According to the reports of the operators, compiled weekly by the Geological Survey and the Fuel Administration, the operation of the mines was seriously interfered with in the early

part of the year by shortage of cars. These data for Maryland are shown graphically in figure 83, combined with the reports from the Somerset field of Pennsylvania, with which Maryland was combined in the organization of the Fuel Administration.

Coal produced in Maryland in 1917.

MICHIGAN.

The production of coal in Michigan in 1918 was 1,464,818 tons, valued at $5,615,097, an increase, compared with 1917, of 90,013 tons, or 6.5 per cent, in quantity and $1,188,783, or 29.9 per cent in value. There was a decrease of 49,000 tons in Bay County, but increases elsewhere in the State. The average number of days worked decreased from 254 in 1917 to 237 in 1918 but the number of men employed increased from 2,406 to 2,558. The average annual output per man increased slightly, from 571 tons to 573 tons, despite the fewer days worked, and the average daily output gained notably, 2.42 tons in 1918 against 2.25 in 1917.

MISSOURI.

There was little change in the quantity of coal produced in Missouri in 1918, as compared with 1917. The production in 1918 was 5,667,730 tons, a decrease of 2,819 tons. Increases in Adair, Barton, Lafayette and a few other of the more important producing counties were offset by decreases in Macon, Randolph, Ray, and other counties. That the production in 1918 did not fall further below that in 1917 was due to the increase in the average daily output per man from 2.44 tons in 1917 to 2.51 tons in 1918. The average number of men employed decreased somewhat, from 9,668 to 9,590, and the number of days worked from 240 to 235. In the western

fields car shortage was at no time in 1918 a serious cause of nonproduction and throughout the year the percentage of full-time operation attained was largely determined by the demand and by the willingness of labor to work when the demand was good.

MONTANA.

The increase in production of coal in Montana in 1918 of 305,816 tons came mainly from Cascade and Musselshell counties (the Great Falls and Roundup fields). The Red Lodge field, in Carbon County, had a decrease of 142,565 tons, or 8 per cent. The total production in 1918 was 4,532,505 tons, valued at $11,444,875, and it set a new high record for the State. Compared with 4,149 men who worked an average of 268 days in 1917, 4,559 men worked an average of 264 days in 1918.

NEW MEXICO.

A decrease in production in 1918 compared with 1917 in the Raton field (Colfax County) of 85,000 tons and an increase in the Gallup field (McKinley County) of 105,000 tons, together with small gains and losses in the several small fields, netted the State an increase of 22,712 tons, or 0.6 per cent. The value of the coal produced in New Mexico in 1918 was $10,787,000, a gain of $3,332,000, or 44.7 per cent, compared with 1917. The average number of days worked declined from 321 in 1917 to 301 in 1918; the number of employees decreased from 4,126 to 4,095; but the average output per man per day gained 3.26 tons in 1918, as compared with 3.02 tons in 1917.

OHIO.

The production of coal in Ohio in 1918 was 45,812,943 tons, valued at $118,095,518, an increase as compared with 1917, of 5,064,209 tons, or 12.4 per cent, in quantity and of $17,198,370, or 17 per cent, in value. The increase was general. Of the counties for which separate statistics are presented, only four—Holmes, Jackson, Mahoning, and Wayne—recorded decreases, and of these counties Jackson, the only one of importance, had a very slight decrease. There was no lack of market for coal from Ohio in 1917 or in 1918 until the end of the year, and the increase was the result of more days worked and more men employed. The number of men employed increased from 45,509 in 1917 to 48,450 in 1918, and the average days worked from 210 to 223. As might be inferred from the fact that the increase in number of men employed was largely in those working on the surface, the average output per man per day declined—from 4.26 tons

to 4.24 tons, but the average annual output increased from 895 tons to 946 tons.

Although the area in which coal from Ohio was permitted to move under the zone system was closely drawn through the summer of 1918, in order to force a large quantity into the Lake trade, the production was in no wise limited on that score. Weekly reports of operating time furnished the Geological Survey and the Fuel Administration by the operators show that in the first half of the year lack of cars was the principal cause limiting production and that until November car shortage was an important factor in the situation.

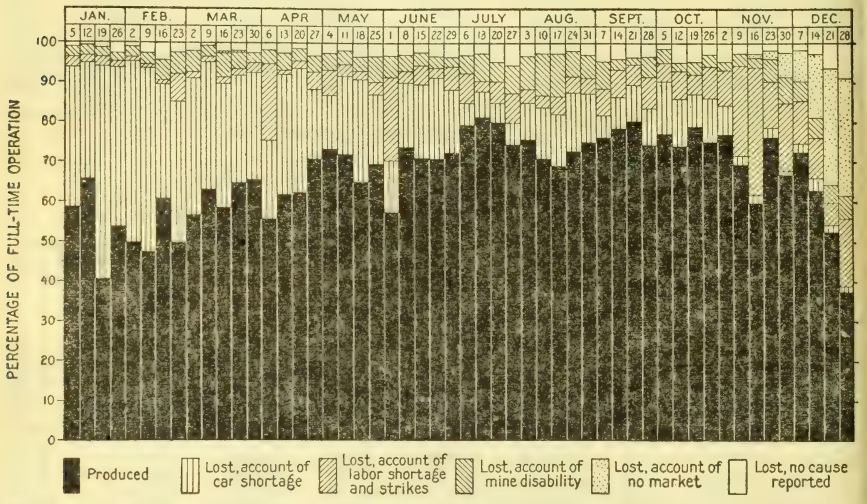

FIGURE 84.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in Ohio, in 1918.

After the armistice, from the middle of November to the end of the year, lack of demand for coal from Ohio became increasingly important as a cause of nonproduction. Under the exigencies of the war program the markets in Ohio, Michigan, and Indiana, that normally consume Ohio coal, were largely supplied with coal from Illinois and Indiana during the summer months, so that with the end of the Lake season Ohio operators were not able to dispose of their product in these normal fall and winter markets, and many were obliged in the winter of 1918–19 to curtail production. These data of operating conditions are shown graphically in figure 84.

Coal produced in Ohio in 1917.

County.	Loaded at mines for shipment (net tons).	Sold to local trade and used by employees (net tons).	Used at mines for steam and heat (net tons).	Made into coke at mines (net tons).	Total quantity (net tons).	Number of employees.			Average number of days worked.

[a] No production in Scioto County.

OKLAHOMA.

The increase in production of coal in Oklahoma in 1918 of 426,603 tons, or 9.7 per cent, was generally shared by all the local districts in the State contributing to the total, Coal County alone recording a decrease. The production in Oklahoma in 1918 was 4,813,447 tons, a new high record for the State, the highest output previously attained having been 4,386,844 tons in 1917. The increase in 1918 was attained by approximately the same number of men working a greater number of days—228 days in 1918 compared with 211 in 1917.

Coal produced in Oklahoma in 1917.

OREGON.

The production of coal in Oregon, which comes almost entirely from the Coos Bay field, has been decreasing for years. The lowest recorded output for the State since 1880 was the record for 1918 of 13,328 tons.

Coal produced in Oregon, 1914–1918.

PENNSYLVANIA

ANTHRACITE.

PRODUCTION.

The production of Pennsylvania anthracite in 1918 was 88,237,575 gross tons, valued at $336,480,347, a decrease, compared with 1917, of 701,542 tons, or 0.8 per cent, in quantity, but an increase of $52,829,624, or 18.6 per cent, in value. The output in 1918 was second only to that in 1917 in the history of the anthracite industry.

The demand for anthracite was unusually strong throughout the year. Early in 1918 the Fuel Administration announced that the available production in the 12-month period beginning April 1, 1918, the coal year 1918–19, would be allotted on the basis of the distribution in the coal year 1916–17, with the exception that anthracite would be denied to many sections of the country, such as the West and South, that had received comparatively small shipments in the past and to certain other sections of the country nearer the anthracite mines that had ample local supplies of bituminous coal for domestic use. In general this scheme of allotment was closely followed from April through December, 1918, for the demand for anthracite did

not slacken, as did that for bituminous, with the signing of the armistice. It was not until the middle of January, 1919, that domestic consumers were satisfied with the supplies of anthracite on hand and, because of the mildness of the winter, ceased to order more coal. A full description of the program of the Fuel Administration with respect to anthracite and the statistics of allotments and deliveries will be found in Part I of the report of the distribution division of the Fuel Administration.

In both the Lehigh and Schuylkill regions production was greater in 1918 than in 1917, but the Wyoming region and Sullivan County recorded decreases. There was a decrease of 2,056,566 tons in the quantity of freshly mined coal, but a substantial increase, 1,254,794 tons, or 20.1 per cent, in the output of washeries, and of 100,230 tons, or 65.8 per cent, in dredged coal. The product of both washeries and dredges is mainly small coal not suitable for domestic use and the increase from those sources did not add to the supply for homes nor help in the immediate and pressing problem of providing domestic fuel.

The total production of Pennsylvania anthracite in 1918 exceeded that in 1913 by 8.0 per cent and that in 1916 by 12.8 per cent, but the output of domestic sizes, pea and larger, in 1918 exceeded that of 1913 by only 0.6 per cent and that of 1916 by 8.7 per cent.

Anthracite produced in 1890–1918.

1911	80,771,488	175,189,392	1918	88,237,575	336,480,347
1912	75,322,855	177,622,626			

[a] Excludes value of coal used at collieries.

The facts that no price was fixed by the Government on sizes of anthracite smaller than pea and that the demand for steam coal in the east was so strong account for the large increase in the production of the steam sizes. The prices established for bituminous coal were such that the producers of the smaller sizes of anthracite could meet the competition of bituminous coal producers to advantage.

The shipments reported to the Geological Survey include those from Sullivan County, the product of dredges, and all local shipments within the region, and amounted in 1918 to 76,721,157 gross tons, valued at $317,522,181 at the breaker, an average value per gross ton of $4.14, as compared with $3.47 in 1917. Shipments of freshly mined anthracite had an average value per ton of $4.27 in 1918, against $3.58 in 1917; the average value of washery product was $2.80 in 1918 and $2.04 in 1917; and the average value of dredge product was $1.66 in 1918 and $1.50 in 1917.

The quantity of anthracite sold locally and used by employees increased from 2,127,109 gross tons, valued at $6,070,907, or $2.85 per ton, in 1917 to 2,387,892 tons, valued at $7,746,256, or $3.24 per ton in 1918.

Anthracite produced in 1917 and 1918.

Anthracite used at the mines and breakers for steam and heat represents more than 10 per cent of the total output. In 1918 the quantity so used was 9,128,526 gross tons, or 10.35 per cent of the total output, compared with a maximum in recent years of 11.25 per cent in 1915. The percentage of fuel required for operating the mines and breakers may be expected to increase in future years because of the greater depth of the workings and because of the mining of thinner beds of coal. The more extensive development of central power stations and the use of lower grades of coal will continue as in recent years to offset the requirement of larger quantities of anthracite as mine fuel.

Production of anthracite in 1918 followed closely the record for 1917 until October, when the epidemic of influenza was severely felt in the mining regions and production decreased sharply to a minimum rate for the year in the middle of November.

Anthracite shipped in 1917 and 1918, by regions and sizes, in gross tons.

[a] Includes quantity reported as culm, buckwheat No. 4, screenings, settlings, silt, mine run, dirt, and slush.

137536°—M R 1918—PT 2——50

The proportions of sizes in the output of the breakers remain fairly constant from year to year. In the years 1913 to 1916 the percentage of freshly mined anthracite marketed in sizes above pea was from 62.2 to 63.3, but in 1917 and in 1918 the percentage increased to 64.7; whereas the percentage of pea size in 1913 to 1916 was from 11.2 to 12.1 but decreased in 1917 to 8.7 and in 1918 to 8.3 for the reason, it is understood, that pea coal was more or less commonly mixed with chestnut, the next larger size. The greatly increased production of washery and dredge coal is reflected in the increase in the percentage of sizes below pea in the total of all production from 26.9 per cent in 1913 and 28.5 per cent in 1916 to 30.3 per cent in 1917 and 31.6 per cent in 1918.

Anthracite shipped, 1913–1918, by sizes, in gross tons.

[a] Does not include shipments from Sullivan County nor from dredges.
[b] The figures for the Lehigh & New England R. R. are not included in 1914, and the totals for this year are therefore not comparable with 1915, 1916, and 1917.

LABOR STATISTICS.

Statistics of labor employed in the production of Pennsylvania anthracite in 1917 and 1918 are given in the following table. In the Wyoming region only were machines reported in use in the mining of anthracite in 1917, but in 1918 two machines were reported in the Schuylkill region and 15 in Sullivan County in 1918. In 1917, 155 machines were used to produce 1,745,735 gross tons; in 1918, 176 machines produced 1,658,495 gross tons. Anthracite recovered from steam-shovel pits in 1917 was 2,054,989 gross tons, compared with 2,107,306 gross tons in 1918. Seventy-six steam shovels were in use in 1917, and 82 in 1918. In 1918 there were 254 active breakers, 76 washeries, and 32 dredges compared with 244 breakers, 59 washeries, and 26 dredges in 1917.

The statistics of strikes, production by machines, and the number of steam shovels in use, as well as the number of men employed, are given in the following tables:

Men employed in the anthracite regions, 1917 and 1918, by regions.

VALUE OF ANTHRACITE.

The value of anthracite reported to the Geological Survey and shown in this report is the value at the breaker, less degradation losses and selling costs. The dollars received from the sale of each size are reported and these amounts are divided by the total shipments of each size, the figure thus obtained representing the average realization price per ton.

The prices at which the sizes of anthracite above pea were sold in 1918 were those established by the Fuel Administration. For a description of the method by which these prices were determined, together with data on the cost of producing anthracite, the reader is referred to the report of the Engineers' Committee of the Fuel Administration; and for the text of the orders establishing the prices reference is made to the publication of the Fuel Administration entitled "General orders, regulations, and rulings of the United States Fuel Administration, including the acts of Congress, Executive orders,

and proclamations of the President pursuant to which the United States Fuel Administration was created and is acting." The prices of anthracite from 1913 through 1918 are discussed in the report[1] on "Prices of coal and coke," 1913–1918, already referred to.

Value of anthracite shipped in 1917, by regions and sizes.

BITUMINOUS COAL.

The production of bituminous coal in Pennsylvania in 1918 was 178,550,741 net tons, valued at $463,159,736, a gain, compared with 1917, of 6,102,599 tons, or 3.5 per cent, in quantity and of $41,890,928, or 9.9 per cent, in value. Important increases in production were recorded in Armstrong, Cambria, Clarion, Fayette, Green, Huntingdon, Indiana, Somerset, and Washington counties, and important decreases reported in Allegheny and Jefferson counties. The bituminous fields of Pennsylvania were divided by the Fuel Administration for administrative purposes into six divisions corresponding to the generally recognized large trade units. The statistics of production in these districts in 1917 and 1918 is given in the following table. It will be noted that each of the six districts had an increase in production in 1918.

Bituminous coal produced in Pennsylvania, 1917–1918, by districts, in net tons.

District.	1917	1918	District.	1917	1918
Central	59,044,092	61,628,709	Connellsville	34,596,903	35,676,500
Northwestern	7,381,328	8,051,383	Somerset	6,589,534	7,193,537
Pittsburgh	47,957,066	48,299,142		172,448,142	178,550,741
Westmoreland, etc	16,879,219	17,701,470			

Of the 34 railroads, large and small, that originate bituminous coal in Pennsylvania, nearly all recorded increases in the quantities of coal shipped from the mines. The increase on the Pennsylvania Railroad of nearly 8,000,000 net tons was greater than the total increase in production in the State, and was nearly 80 per cent of the total increase in shipments of bituminous coal from the mine to market. The more important roads in which there were decreases in the quantities of bituminous coal originated were the Huntingdon & Broad Top Mountain, Pennsylvania lines west of Pittsburgh, Pittsburgh & Lake Erie, Pittsburgh & Susquehanna, and Pittsburgh & West Virginia.

Shipments from the mines, in other words, coal going to market, increased from 128,966,000 net tons in 1917 to 137,493,000 tons in 1918, a gain of 8,527,000 tons, or 6.6 per cent. Coal coked at the mines decreased from 34,707,000 tons to 32,460,000 tons, or by 7 per cent.

The number of days worked by the bituminous coal mines in Pennsylvania increased from 261 in 1917 to 269 in 1918, and to this gain is attributed the increase in production, as the average daily output per man employed increased very slightly, from 3.80 tons to 3.81 tons, and the total number of men increased by only a few hundred, from 173,968 to 174,306. The average daily output per man, all employees considered, was maintained, however, only by increased efforts on the part of the miners, for the number of underground employees decreased from 143,687 to 140,502.

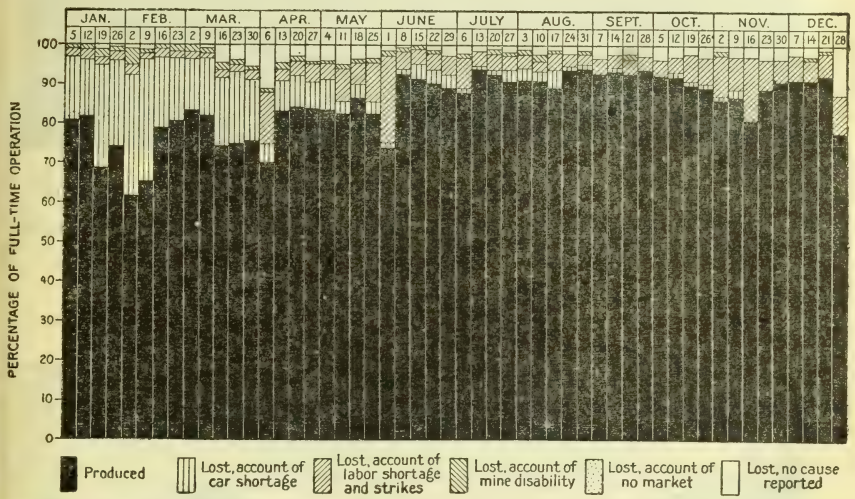

FIGURE 85.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in central Pennsylvania, 1918.

The average value per ton at the mines of bituminous coal produced in Pennsylvania increased from $2.44 in 1917 to $2.59 in 1918.

Reports on working time made by the operators weekly to the Geological Survey and the Fuel Administration in 1918 are shown in the diagrams (figs. 83, 85, 86, and 87). The central Pennsylvania field (fig. 85), in common with all other coal fields of the country, suffered from car shortage in the early months of the year. Transportation conditions improved in May and June, and through the remainder of the year they were exceedingly good.

In the Pittsburgh and Somerset districts car shortage was the principal factor limiting production (figs. 83 and 86) in the first half of 1918 and was also an important factor at periods in the last half of the year. Labor shortage and strikes appear to have been important factors in limiting output in northwestern Pennsylvania.

SOUTH DAKOTA.

The production of lignite in Dewey, Harding, and Meade counties, South Dakota, decreased 863 tons and the production in Perkins County increased 763 tons, the net result being a decrease for the State of 100 tons. The lignite deposits of South Dakota are in a sparsely settled region and not generally within reach of the railroads. The lignite produced is for local use in the northwestern part of the State.

Lignite produced in South Dakota in 1917.

TENNESSEE.

The production of coal in Tennessee in 1918 was 6,831,048 tons, valued at $19,305,203, a gain of 636,827 tons, or 10.3 per cent, in quantity and of $5,712,205, or 42 per cent, in value. The average value per ton increased from $2.19 in 1917 to $2.83 in 1918. The average number of days worked increased from 241 to 265 and the number of men employed increased slightly from 10,421 in 1917 to 10,694 in 1918, the gain being about equally divided in number between men employed underground and on the surface. The average output per man per day decreased from 2.46 tons to 2.41 tons, but because of the greater number of days worked the average annual output per employee increased from 594 tons to 639 tons. Marion was the only county in Tennessee for which the statistics are shown separately to record a decrease in production.

The weekly statistics of operating conditions collected by the Geological Survey and the Fuel Administration for Tennessee are combined with southeastern Kentucky and are shown in figure 80 (p. 757). It will be noted that in this district the principal cause limiting production for the first nine months of the year was lack of cars and in the last quarter was labor and to a certain extent lack of market. The influenza epidemic was largely responsible for the low production in October and November, 1918.

Coal produced in Tennessee in 1917.

TEXAS.

The production of coal in Texas in 1918 was 2,261,135 tons, of which 1,074,183 tons was bituminous coal and 1,186,952 tons was lignite. Compared with 1917, the total in 1918 was a decrease of 94,680 tons, or 4 per cent. The production of bituminous coal decreased 185,093 tons, or 15 per cent, and the production of lignite increased 90,413 tons, or 8 per cent. The principal cause of the decrease in production of bituminous coal was lack of men, as the demand for this grade of coal was good throughout the year. In 1918 there were employed in the bituminous coal mines 2,349 men who worked an average of 273 days, compared with 2,793 men and 274 days in 1917. The number of men engaged in the mining of lignite in 1918 was 1,587, compared with 1,582 in 1917. The lignite mines averaged 244 working days in 1917 and the same in 1918.

UTAH.

The notable increase in the production of coal in Utah in 1918, from 4,125,230 tons in 1917 to 5,136,825 tons in 1918, a gain of 1,011,595 tons, or 24.5 per cent, was shared in all producing districts. Carbon County, the largest producer, had an increase of 905,301 tons. The increase was made possible by a continuous demand, more men, and an increase in the days worked.

Coal produced in Utah in 1917.

VIRGINIA.

The production of coal in Virginia in 1918 was 10,289,808 tons, valued at $25,865,895, a gain, compared with 1917, of 202,717 tons, or 2 per cent, in quantity and of $5,740,182, or 28.5 per cent, in value. The more important increases were in Dickinson and Wise counties. Slight decreases in output were reported from Russell and Tazewell counties. The year 1918 did not differ materially from 1917 for the coal industry in Virginia; a strong demand for coal prevailed throughout the two years; the number of men employed varied only from 11,168 in 1917 to 11,004 in 1918; the average number of days worked increased by 4, from 273 to 277. Virginia and Alabama were the two fields in the east that suffered least from car shortage.

FIGURE 88.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, in the southwestern and Chinch Valley districts of Virginia, in 1918.

The reports of operating conditions as reported by the operators to the Geological Survey and the Fuel Administration are shown in the accompanying diagram (fig. 88). In the first half of the year both car and labor shortage contributed to the lack of full-time operation, although car shortage was not, except in a few weeks in the early months of the year, a factor of importance. In the last quarter of

1918 the epidemic of influenza caused a considerable cessation of operations.

WASHINGTON.

A new high record for production of coal in Washington was set in 1918 with an output of 4,082,212 tons, a gain over 1917 of 72,310 tons, or 1.8 per cent. The Roslyn field (Kittitas County), east of the mountains, and Pierce County recorded slight decreases in 1918, and King, Lewis, Thurston, and Whatcom counties had increases. The number of men employed decreased from 5,312 in 1917 to 5,109 in 1918, but the average number of days worked increased from 271 to 275.

WEST VIRGINIA.

The production of coal in West Virginia in 1918 was 89,935,839 net tons, valued at $230,508,846, a gain of 3,494,172 tons, or 4 per cent, in quantity and of $29,849,478, or 14.9 per cent, in value. Among the larger producing counties, Fayette, Kanawha, McDowell, and Mercer recorded substantial decreases and Harrison, Logan, Monongalia, Preston, and Raleigh recorded considerable increases. In general, the Panhandle district comprising Ohio, Brooke, Hancock, and Marshall counties had a substantial increase in production; the Fairmont and neighboring districts in the northern part of the State had increased production, as did the Logan field in the southern part of the State; and the Kanawha district proper, on the main line of the Chesapeake & Ohio Railway, had a decrease, as did also the smokeless fields.

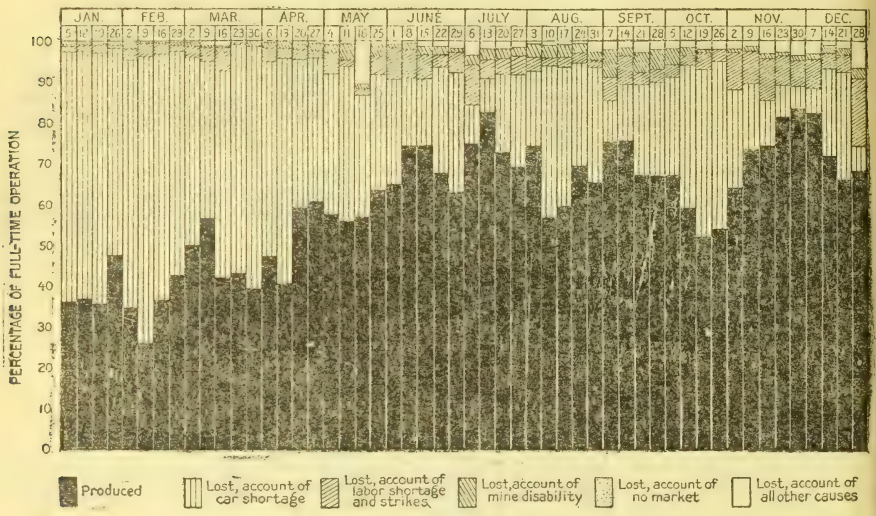

FIGURE 89.—Percentage of full-time operation of coal mines in the high-volatile coal fields of southern West Virginia, in 1918.

There was no lack of demand for coal from the fields in West Virginia in either 1917 or 1918, and the relative increases and decreases were directly attributable to relative supplies of labor and of transportation, with the exception that through failure at frequent periods in 1917 and in 1918 of central power used by the coal mines production in both the Kanawha and the New River districts was lost that, in part at least, might otherwise have been obtained.

For the State as a whole, the average number of days worked was 238 in 1918, as against 225 in 1917; the average output per man per day was 4.22 tons in 1918, compared with 4.35 in 1917; and the average annual output per man was 1,005 tons, as compared with 978 tons. The total number of men increased slightly, from 88,422 to 89,530.

The percentages of full-time operation and of losses by causes as reported by the operators to the Geological Survey and Fuel Administration in 1918 for the three principal producing districts are shown in the diagrams (figs. 89, 90, 91). In the first half of 1918 car short-

age was the principal factor limiting production over the State. In the last half of the year labor shortage was the limiting factor of greatest importance in the smokeless fields and was of about equal

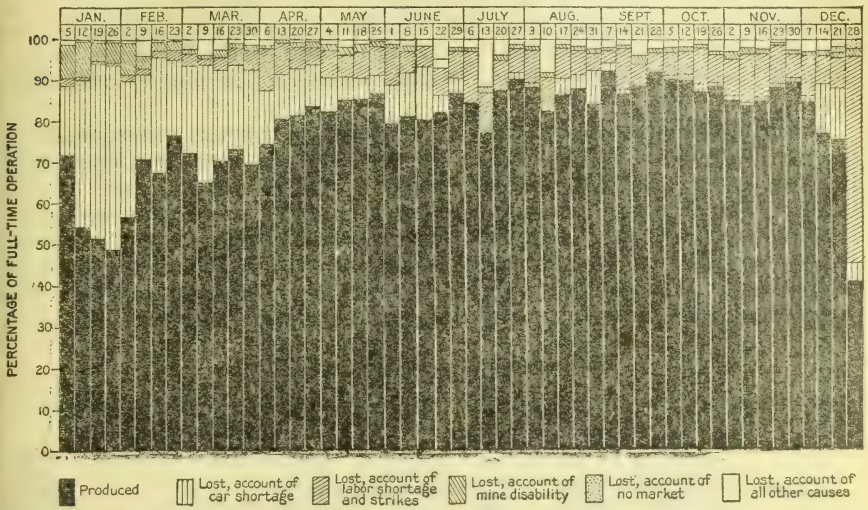

FIGURE 90.—Percentage of full-time operation of coal mines in the low-volatile coal fields of West Virginia, in 1918.

importance with car shortage in the high volatile fields in the southern part of the State. In the Fairmont field lack of cars was a factor of importance throughout 1918, though more prominent in

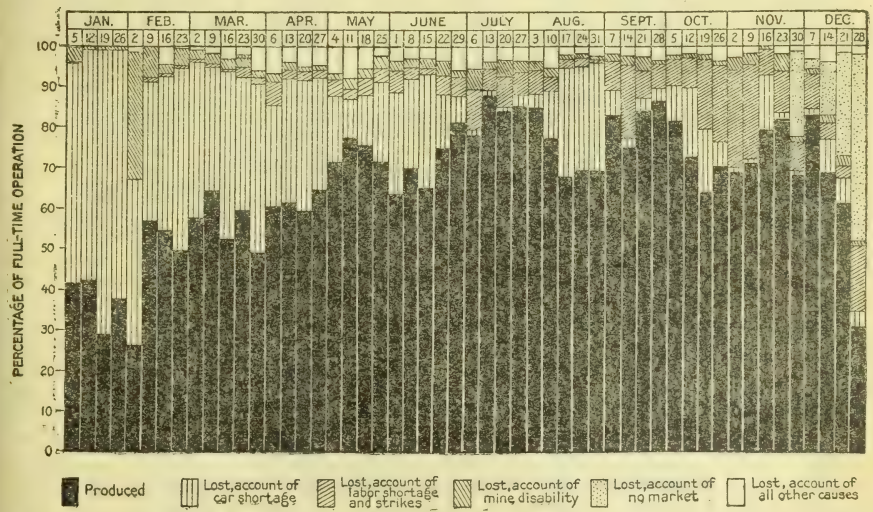

FIGURE 91.—Percentage of full-time operation of coal mines and of losses of running time, by causes and by weeks, Fairmont district of West Virginia, in 1918.

the first half than in the second half of the year. The reason for the failure of the railroads to show the same improvement in the Fairmont as in other districts lies principally in the fact that the

Fairmont district is overdeveloped as regards coal mines with respect to the capacity of the railroads to serve the mines and transport the loaded cars out of the field to the markets. Furthermore, the Baltimore & Ohio Railroad, the principal carrier serving the fields, is primarily an originating and not a delivery road, and difficulty was encountered throughout the year 1918 and even in more nearly normal times in getting back to this railroad the empty cars that belong to it.

It will be noted further that lack of demand was not experienced in any of these fields until the last few weeks of the year and then only noticeably in the high-volatile fields in the southern part of the State. The Fairmont and smokeless fields find their principal markets in the East; the Kanawha, Logan, and Thacker districts depend in normal times to a considerable extent and under the zoning system in effect in 1918 almost entirely on the western market; and the western market was dull after the signing of the armistice.

Coal produced in West Virginia in 1917.

County.	Loaded at mines for shipment (net tons).	Sold to local trade and used by employees (net tons).	Used at mines for steam and heat (net tons).	Made into coke at mines (net tons).	Total quantity (net tons).	Number of employees.			Average number of days worked.

f Includes Grant, Summers, and Wetzel.

WYOMING.

The production of coal in Wyoming increased from 8,575,619 tons in 1917 to 9,438,688 tons in 1918, a gain of 863,069 tons, or 10.1 per cent. Substantial increases were recorded in Sheridan County and in the Rock Spring field (Sweetwater County), but the Kemmerer field (Lincoln County) had a small decrease. The number of men employed increased from 7,358 in 1917 to 7,554 in 1918, and the average number of days worked increased from 246 to 268. The average output per man per day, however, dropped from 4.74 tons in 1917 to 4.66 in 1918, but, because of the greater number of days worked, the average annual output increased from 1,165 tons in 1917 to 1,249 tons in 1918—the highest average recorded in any State in 1918.

LIME.

By G. F. Loughlin and Herbert Insley.[1]

INTRODUCTION.

The growing interest in the many features of the lime industry was hastened by war conditions, especially in 1918, when it became imperative for the War Industries Board and other Government organizations, as well as for the producers and consumers of lime in general, to know the distribution of lime plants in the United States and the uses for which their product was sold, in order that the more essential demands for lime could be supplied most economically. To this end the United States Geological Survey was requested to prepare a map setting forth this information for the War Industries Board and the War Service Committee.

The location and relative production of different manufacturing centers and the kinds of lime produced in each have proved to be of such general interest that these features of the map are here shown on Plate VI. This map, it is hoped, will be followed by a map showing, in addition to the present data, the extent of high-calcium and high-magnesium formations in so far as they can be separately mapped and also by a bulletin describing the limestones and dolomites of the country.

Inquiries from the war boards and commissions also called for statistical information in much more detail than it had heretofore been believed practicable or even possible to collect. The Geological Survey was able to supply some of this information from unpublished miscellaneous records, but the remainder had to be obtained by request directly from producers, many of whom had not kept such detailed records of their sales. Because of the importance of these details and the desirability of having itemized data on production in times of peace and war, and because also of the more practical use now made of statistics by the more progressive lime manufacturers, the statistical blanks sent out by the Survey in 1918 called for a much greater subdivision of sales according to uses than ever before. The results of the canvass are most conspicuous in the tables showing lime sold to chemical works and miscellaneous manufacturing industries grouped under "other uses." Collection of this great amount of information has necessarily delayed completion of the report, but the present and future value of the results justify the delay.

Another feature of this report is the introduction of several diagrams showing changes in the value and prices of lime and the quantities sold for different uses. Attention is particularly directed to Plate VIII, which shows the average prices for different kinds of lime, and to figures 94 and 95, which show progressive changes in the relative quan-

[1] The statistical tables of this report were prepared by Miss A. T. Coons, with the exception of those on imports and exports, which were compiled from records of the Bureau of Foreign and Domestic Commerce by J. A. Dorsey, both of the United States Geological Survey.

tity of lime devoted to the more important uses, notably the prevailing decline in building lime and, in recent years, of agricultural lime and the general increase in chemical and "other" lime.

On February 3, 1919, a preliminary estimate was published by the Survey giving the total quantity of lime produced and sold in the United States and the quantity produced and sold in the leading States. A general review of the industry by districts was included, as well as a survey of the conditions affecting the quantity of lime sold for the different uses. This preliminary estimate closely approximated the actual figures. The estimated total quantity of lime produced and sold was 3,028,000 tons, which was only 178,016 tons short of the actual quantity—an underestimate of about 5.6 per cent.

The situation in the lime industry in 1918 was such as to make necessary many radical readjustments. Producers who were not able or willing to make such readjustments were forced to close down their plants. This was especially true of the producers who did business on a very small scale.

The great handicaps to production in 1918 were scarcity of labor, scarcity of coal and other supplies, and war restrictions on building operations. The scarcity of labor, coal, and other supplies made their cost much higher than in preceding years. To meet this rising cost, producers tried to increase the price of lime in proportion, but in many sections of the country this increase was impossible owing to the keenness of competition. Where fuel was very scarce, producers were often compelled to run their kilns intermittently, thus further increasing the cost of production. War restrictions on building decreased the demand greatly in those States where lime was manufactured principally for building; but in States where much lime is used in manufacturing industries the demand was fair or even very good, the increased demand for chemical or "other" lime usually making up for the lack of demand for building lime. As a rule, it was inability to take care of the demand, owing to scarcity of labor and lack of fuel, that caused the decrease in output. Scarcity of labor apparently played as great a part in cutting down the output as lack of fuel. When labor could be obtained it was usually of an inferior quality. Lack of shipping facilities was also a great handicap to producers, although it did not seem so great a factor in the decrease of production as scarcity of labor and fuel and the war restrictions.

LIME SOLD IN 1918.

Lime burned and sold in the United States in 1909–1918.

	Quantity (short tons).	Value.[a]	Average price per ton.	Number of plants in operation.

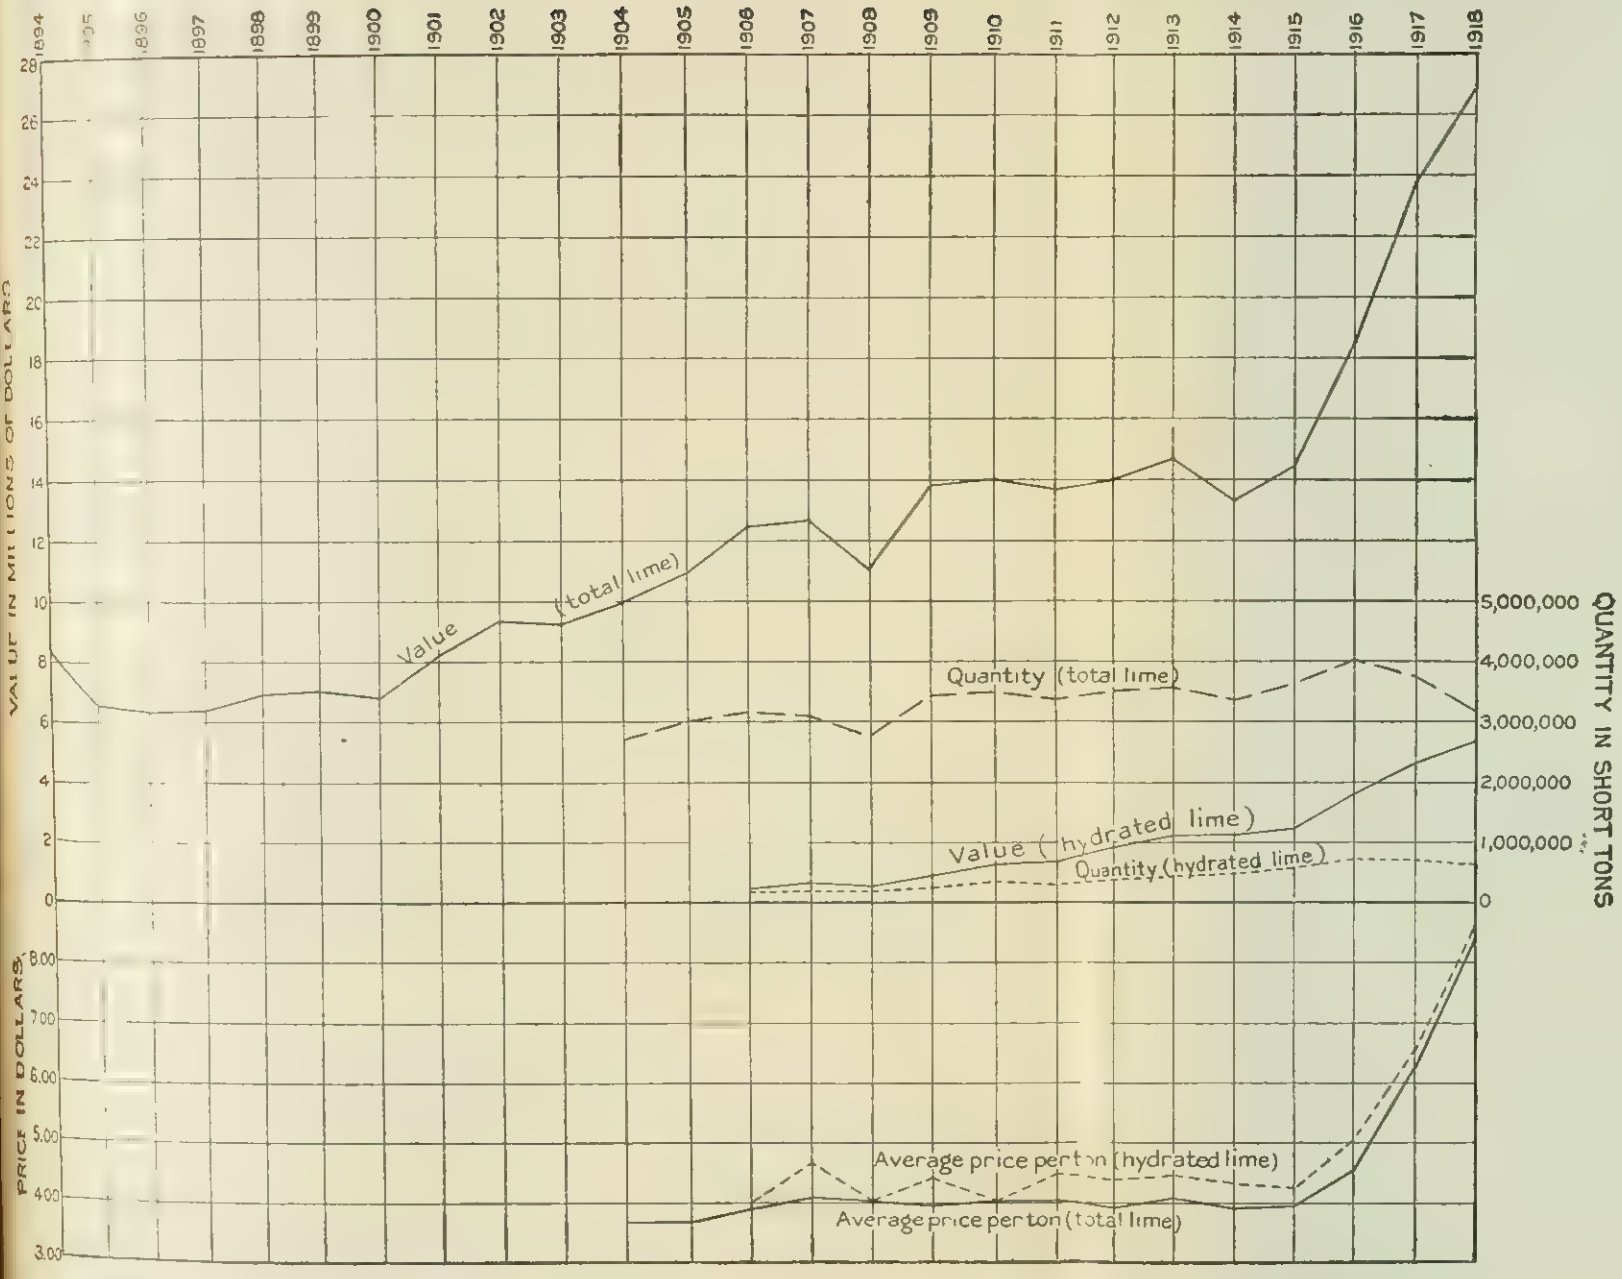
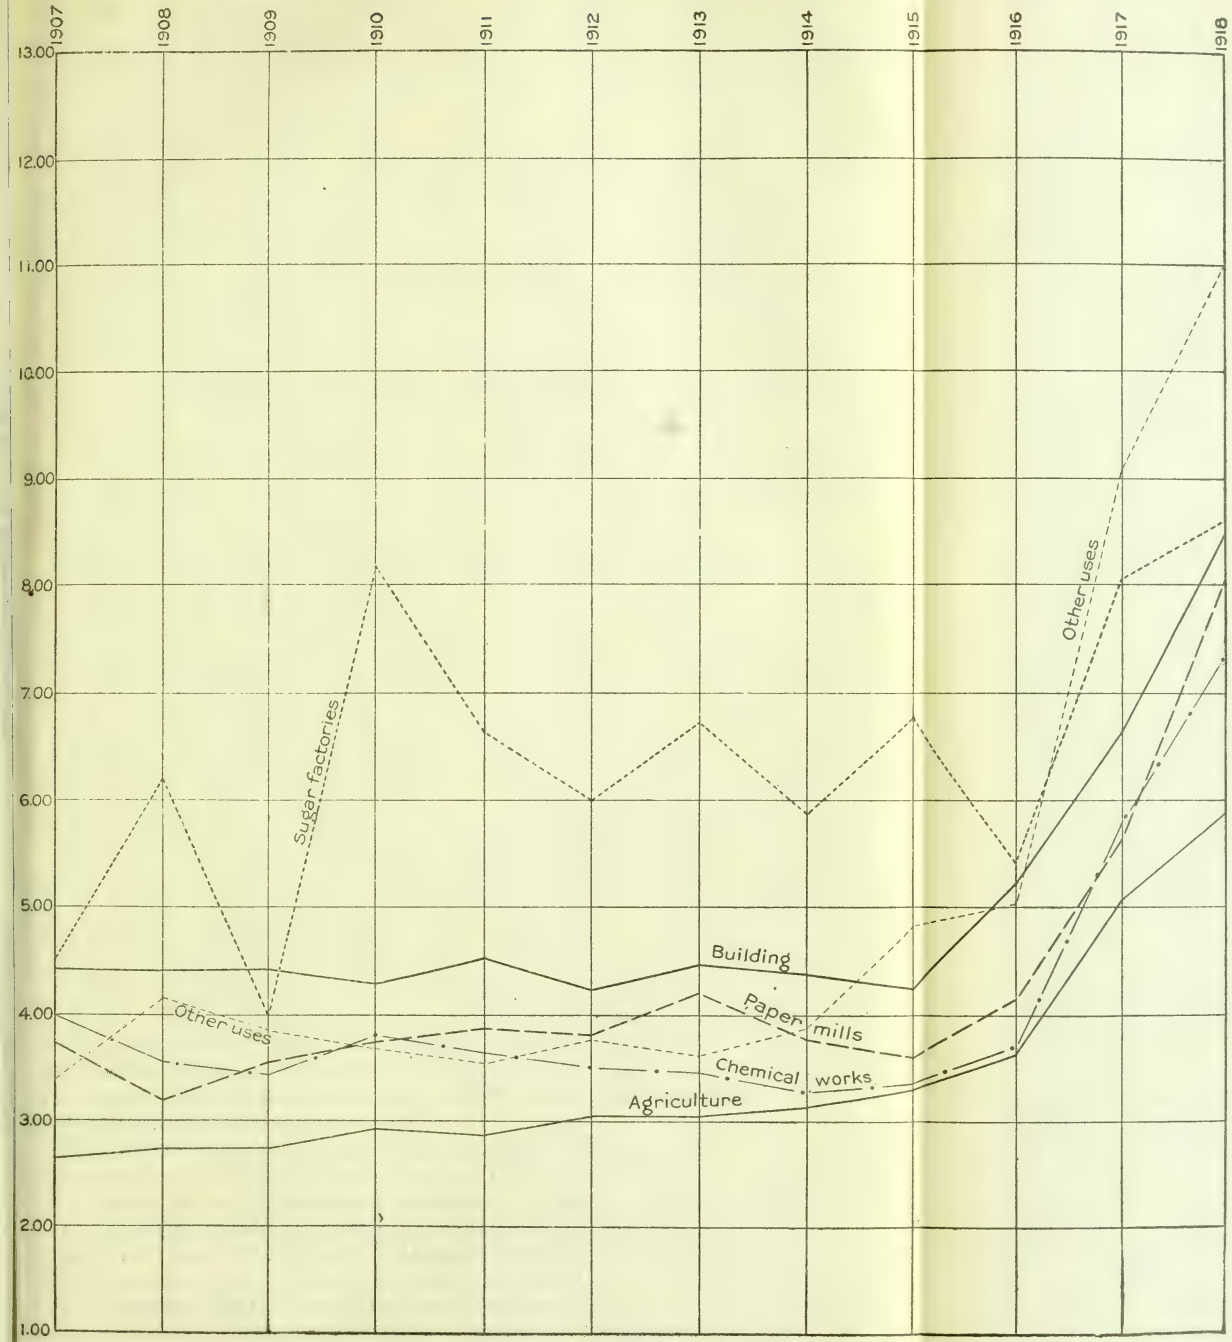
MAP OF THE UNITED STATES SHOWING DISTRIBUTION OF ACTIVE LIME-PRODUCING DISTRICTS IN 1918.



FLUCTUATIONS IN VALUE, QUANTITY, AND AVERAGE PRICE PER TON OF TOTAL LIME AND HYDRATED LIME.



AVERAGE PRICE PER TON OF LIME FOR DIFFERENT USES, 1907-1918.

The total quantity of lime sold in 1918 was 3,206,016 short tons, valued at $26,808,909—a decrease in quantity of 580,348 tons, or 15 per cent, but an increase in value of $3,001,032, or 13 per cent, compared with the production in 1917. The greatest quantity of lime sold in any one year was recorded in 1916, when 4,073,433 tons was produced and sold. In value, however, the highest mark was reached in 1918 (Pl. VII).

The average price per ton of lime increased from $6.29 in 1917 to $8.36 in 1918. This was an increase of 33 per cent over the price for 1917 and of 113 per cent over the price for 1914 (Pls. VII and VIII). The increase in price was due in great part to the increase in the cost of labor, fuel, and all other supplies. Decrease in price in 1918 was recorded only in Hawaii, Montana, and Wyoming, all small producing States. The greatest increase in price was in Florida, where the average price per ton rose from $5.74 in 1917 to $13.58 in 1918. The average price per ton in Wyoming was $18.75, the highest price in any State, although this was in fact a decrease from $21.93 a ton in 1917. The high price in Wyoming was undoubtedly caused by the isolation of the State and the difficulty of transportation to and from other States. The fact that both Wyoming and Rhode Island showed comparatively small outputs from single producers probably also accounts in part for the high price per ton.

The plants in operation in 1918 numbered 496, the smallest number yet recorded by the Geological Survey, and a decrease from 1917 of 99 plants. The percentage of decrease in the number of plants (16.6 per cent) was approximately the same as the percentage of decrease in quantity of lime (15.3 per cent), although in the last few years the tendency has been for the decrease in plants to be much more rapid than the decrease in production. The greater number of plants that discontinued operations in 1918, as in former years, were very small producers. The fact that fewer plants shut down in 1918 than in either 1917 or 1916 suggests that the elimination of the small strictly local producer is approaching completion.

Lime in 1918 was burned and sold in 40 States and 2 Territories. Sales increased in only 4 States and in Porto Rico. Kentucky showed the greatest percentage of increase, 161 per cent, although this was an actual increase of only 1,161 tons. The greatest actual increase was recorded in Ohio, a gain of 10,037 tons. The number of plants in Ohio, however, increased only 1—from 31 in 1917 to 32 in 1918. All the States except Arkansas, California, Maine, Minnesota, New Jersey, Oregon, Virginia, West Virginia, and Wisconsin showed increases in value of output in 1918. In all these nine States the percentage of decrease in quantity was much greater than the percentage of decrease in value.

The three leading States in the quantity of lime sold in 1918 were the same as in 1917—Pennsylvania, Ohio, and Virginia. The next four show some differences, however. Missouri was fourth, West Virginia fifth, Michigan sixth, and Massachusetts seventh. In 1917 West Virginia was fourth, Missouri fifth, Wisconsin sixth, and Michigan seventh. Wisconsin dropped from sixth to ninth place in 1918. Seven States exceeded the million-dollar mark in value of output in 1918, compared with six in 1917. Pennsylvania exceeded $6,000,000. Ohio $4,000,000, and Virginia $1,600,000.

Lime sold in the United States in 1917.

CONDITIONS IN COMMERCIAL DISTRICTS.

The National Lime Association, through the special committee on constitution and by-laws, appointed in August, 1919, revised the division of the United States into 14 commercial districts. The 14 districts now recognized are as follows (Pl. VI):

1. Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Rhode Island, and that portion of New York tributary to New York City.
2. Eastern Pennsylvania, New Jersey, eastern portion of West Virginia, Delaware, and Maryland.
3. Western Pennsylvania, western New York, and western West Virginia.
4. Virginia, North Carolina, and South Carolina.
5. Ohio.
6. Michigan.
7. Illinois, Indiana, and eastern Missouri.
8. Wisconsin.
9. North Dakota, South Dakota, Minnesota, and Iowa.
10. Kentucky and Tennessee.
11. Mississippi, Alabama, Georgia, and Florida.
12. Western Missouri, Nebraska, Kansas, Oklahoma, Arkansas, Louisiana, Wyoming, and Colorado.
13. Texas and New Mexico.
14. Territory west of the Rocky Mountains.

Lime sold in the United States in 1918 and 1917, by districts.

District.	Hydrated lime, 1918.		Total lime, 1918.		Total lime, 1917.		Increase or decrease in 1918 (per cent) (total lime).		Average price per ton, total lime.

[a] Included in "Undistributed."
[b] Virginia only; North Carolina included in "Undistributed."
[c] Alabama only; Florida included in "Undistributed."
[d] Hawaii and Porto Rico included in "Undistributed."

District No. 1, which includes all the New England States and part of New York, produced 380,311 tons of lime, valued at $3,625,047 in 1918, a decrease of about 20 per cent in quantity and an increase of 0.6 per cent in value, compared with 1917. The average price per ton in 1918 was $9.53—an increase of $1.94 over the price for 1917. The quantity of hydrated lime produced amounted to 26,586 tons. Reduced production in this district seems to have been due principally to lack of fuel and war restrictions on building. About 50 per cent of New England's production in normal times is used in the building industries. The demand for chemical (and "other") lime was better than usual. A large portion, 37 per cent, of the lime produced in this district is used by paper mills.

The production of district No. 2 (eastern Pennsylvania, New Jersey, eastern West Virginia, and Maryland) amounted to 871,890 tons, valued at $7,294,192. Of this, 185,067, tons valued at $1,535,322, was hydrated lime. The total quantity showed a decrease of about 20 per cent compared with 1917, although the value showed an increase of 9 per cent. The average price per ton rose from $6.15 in 1917 to $8.37 in 1918. Manufacturers in this district reported very good demand. In Pennsylvania two large companies reported that the demand as a whole was as good or better than normal, although the demand for building lime was much less.

The total production in district No. 3 (western Pennsylvania, western New York, and western West Virginia) was 211,332 tons, valued at $1,420,601—a decrease in quantity of 13 per cent and an increase in value of 13 per cent. The average price per ton was $6.72, an advance of $1.54 over the price for 1917. The quantity of hydrated lime produced amounted to 21,205 short tons. Industrial conditions were about the same as for district No. 2. In New York the high price of coal was one of the greatest difficulties encountered. The output of the recently built plant of the Kelley Island Lime & Transport Co., at Buffalo, N. Y., is included in the production of this district.

In district No. 4 (Virginia, North Carolina, and South Carolina) there was a decrease in quantity of about 19 per cent and a decrease in value of 11 per cent. Only one company operated in North Carolina and none in South Carolina. The average price per ton increased from $5.96 in 1917 to $6.59 in 1918. The quantity of hydrated lime produced increased somewhat over the quantity in 1917. The decreased output of lime was more likely due to increased costs and lack of fuel than to poor demand. Several manufacturers from Virginia reported good demand for agricultural lime and excellent demand for chemical and "other" lime. About half of the lime from this district was used by chemical works and manufacturing plants.

Production in Ohio, the fifth district, amounted to 489,893 tons, valued at $4,640,536. This was an increase in quantity of 2 per cent and an increase in value of 56 per cent over the production for 1917. The average price per ton advanced from $6.20 in 1917 to $9.47 in 1918. Hydrated lime amounted to 234,902 tons, valued at $2,060,-369. The increase in quantity was due mainly to "other" lime and partly to agricultural lime, which offset the large decrease in building lime. Producers in Ohio (including some of the largest lime producers in the United States) seemed generally very optimistic about conditions and reported good demand with high prices and correspondingly high costs.

The State of Michigan constitutes the sixth district. Here production amounted to 134,813 tons—a decrease of 1 per cent compared with production in 1917. In value, however, production showed an increase of 33 per cent. The average price per ton ($8.80) was an increase of $2.23 over the price in 1917. There was a large demand of lime for chemical uses in this State, but the demand for building lime declined to almost nothing.

District No. 7 (Illinois, Indiana, and eastern Missouri) reported a production of 322,596 tons—a decrease of 12 per cent compared with the production of the preceding year. The value, on the other hand, increased 22 per cent. This district, like many others, showed an increased demand for chemical and "other" lime, but a greatly decreased demand for building lime. Lime for use in steel plants also had an increased demand. Several new developments were reported from this district. At Logansport, Ind., a lime plant was put into operation by the Logansport Lime & Stone Co., and at Salem the Louisville Lime & Cement Co. was succeeded by the Hoosier Lime Co. In Missouri the Bluff City Lime & Cement Co. started operations at the quarry of the Star Lime Co., at Hannibal, which had not been in operation for some time. One plant in Illinois that was idle in 1917 resumed operations.

The eighth district (Wisconsin) produced 109,303 tons of lime in 1918, valued at $740,700—a decrease in quantity of 36 per cent and in value of 29 per cent. This was the greatest decrease in either quantity or value reported from any one of the 14 districts. This unusually great decrease was due to the fact that practically all of Wisconsin's lime is used for building purposes. The average price per ton, $6.78, represented an advance of only 66 cents over the price for 1917.

The ninth district comprises North Dakota, South Dakota, Minnesota, and Iowa. North Dakota produces no lime. The production in this district showed a decrease of 24 per cent, compared with the total production for 1917. In value there was a decrease of 11 per cent. The average price per ton advanced from $6.83 in 1917 to $7.95 in 1918. The total production of this district amounted to less than 25,000 tons. The demand for lime for paper mills and tanneries was reported as very good. Demand for building lime decreased greatly.

District No. 10 (Kentucky and Tennessee) produced 108,411 tons of lime, valued at $697,375, an increase of 6 per cent in quantity and of 37 per cent in value. This district and the fifth district were the only ones showing an increase in quantity in 1918. The average price per ton increased from $4.96 to $6.43. The demand for chemical and "other" lime, especially for use in munitions plants, was reported as very good. There was a decreased demand for lime for sugar factories. The plants of the Wheeler Lime Manufacturing Co., near Nashville, the Inter-State Lime Corporation, at Bristol, and the Clinchfield Portland Cement Corporation, at Kingsport, were new developments in Tennessee in 1918.

District No. 11 includes Mississippi, Alabama, Georgia, and Florida, but only two of these States, Alabama and Florida, were producers. The quantity of lime showed a decrease of about 30 per cent compared with 1917, whereas the value showed an increase of about 14 per cent. The average price per ton increased from $5.74 in 1917

to $9.31 in 1918. Shortage of labor, cars, and fuel caused decreased production in this district.

District No. 12 includes western Missouri, Nebraska, Kansas, Oklahoma, Arkansas, Louisiana, Wyoming, and Colorado, but only six of these States are producers. The total production in 1918 amounted to only 77,838 tons, a decrease of 20 per cent compared with 1917. In value the increase was 4 per cent. The average

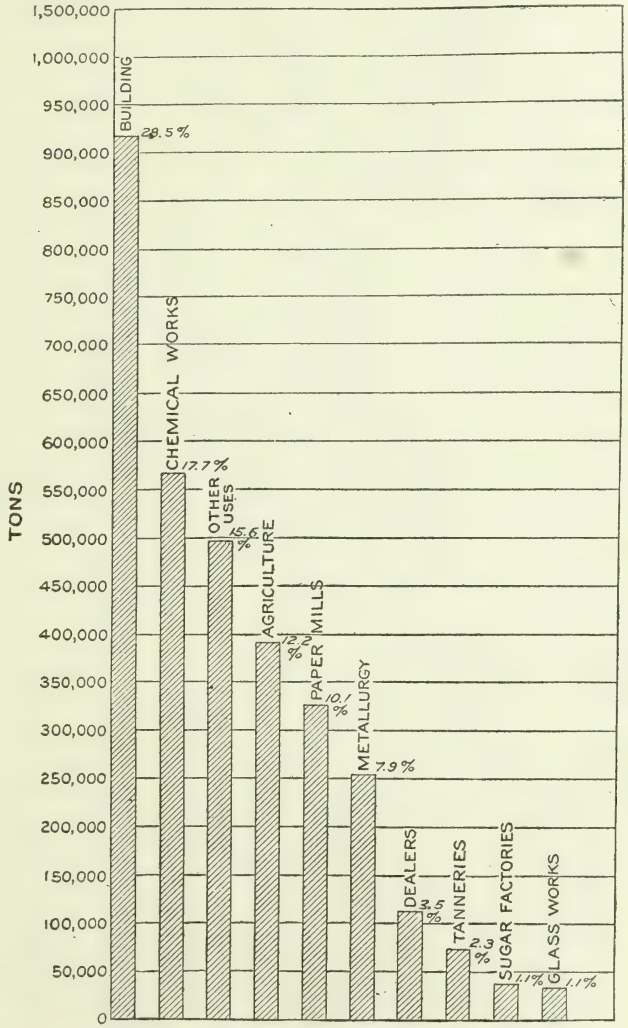

FIGURE 93.—Production of lime for specified uses in 1918.

price per ton was $9.01, an increase of $2.08 over the price for 1917. The large decrease in production was due to the decreased demand for building lime. A great percentage of the lime produced in this district is used for building purposes. In this district the plant of the Kansas City Hydrated Lime Co., Fort Scott, Bourbon County, Kans., resumed operations after having been idle several years.

In district No. 13 (Texas and New Mexico) the production of lime decreased, but the value was about equal to the value in 1917.

The fourteenth district, including all the States west of the Rocky Mountains, produced 111,729 tons of lime in 1918. The value of the lime produced was almost the same as in 1917, although the average price per ton advanced from $7.45 to $9.80. There was

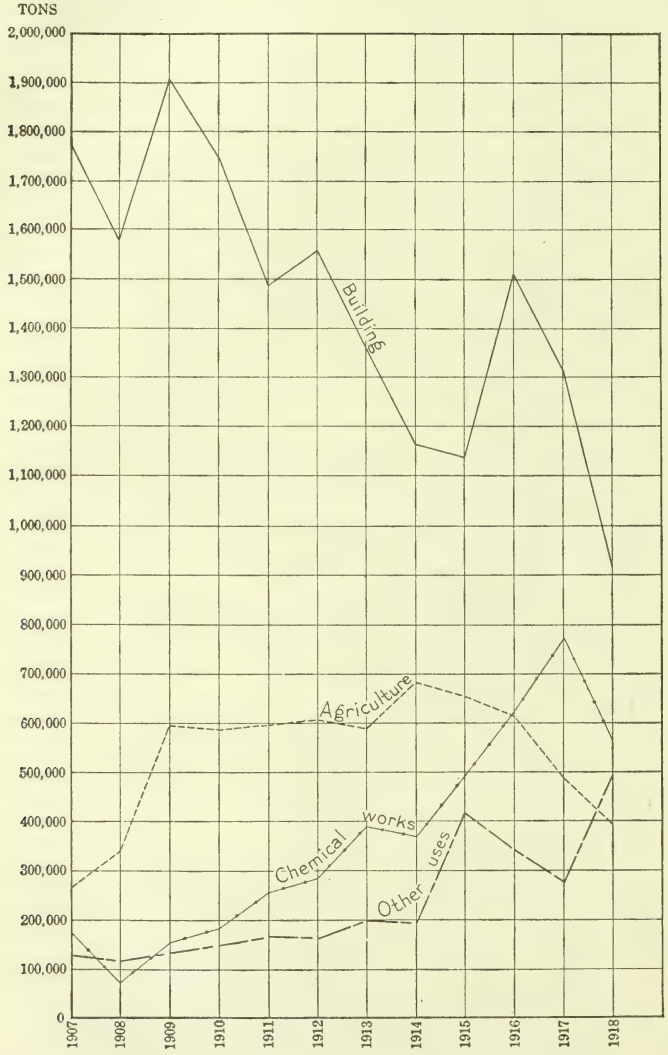

FIGURE 94.—Production of lime for principal uses, 1907–1918.

a great decrease in the lime sold to sugar factories which in normal times forms a large proportion of the total quantity of the lime produced in this district. Demand was poor for building lime, and was fair for agricultural and chemical lime. Part of the decrease in production was due to lack of shipping facilities for exporting the product.

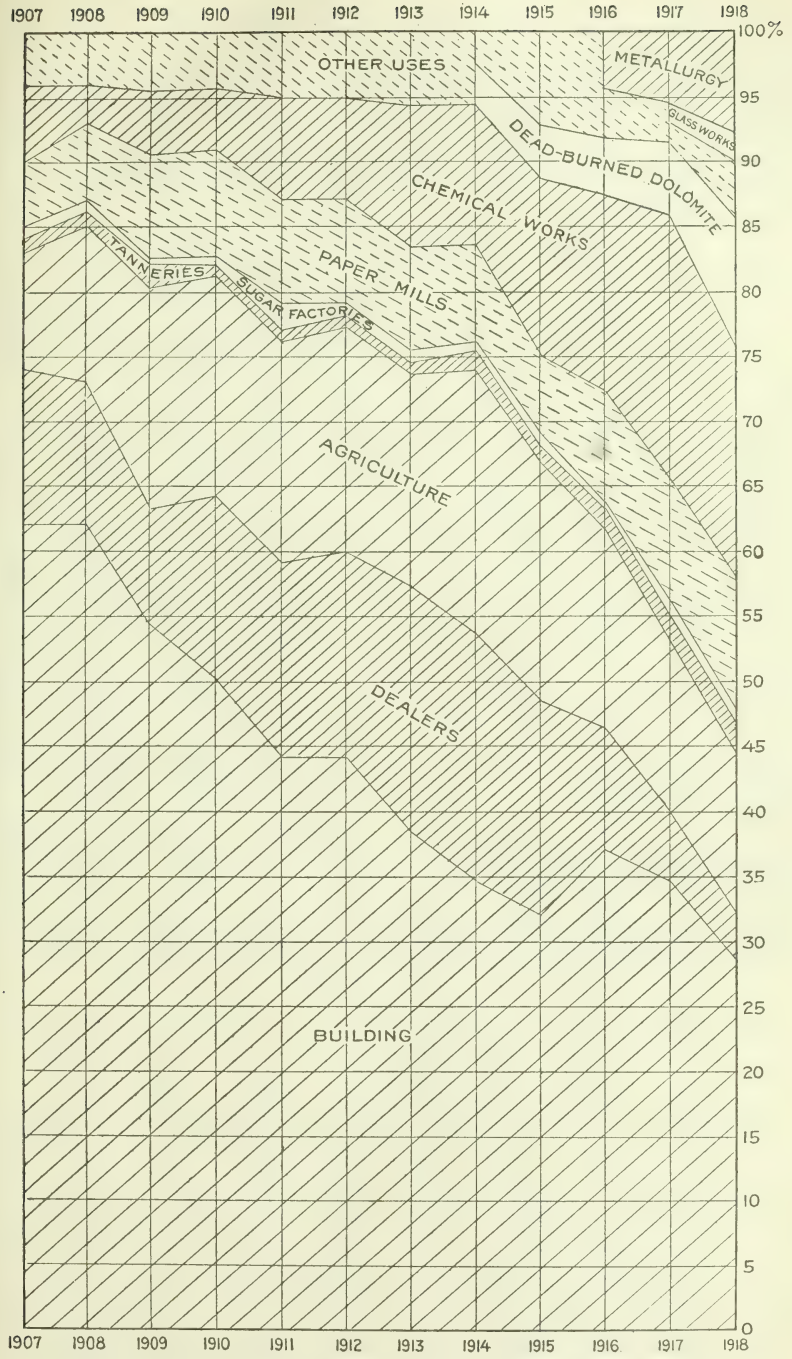

FIGURE 95.—Percentage of lime produced for different uses, by quantity, 1907–1918.

USES.

Sales of lime in the United States in 1917 and 1918, classified according to principal uses, are shown in the following table. Figure 94 is a diagram showing the fluctuation in the actual quantities of lime sold for the four principal uses from 1907 to the present time. Figure 95 is a diagram showing what percentage of each year's total production was consumed in each of the classified uses from 1907 to the present time.

Lime sold in the United States in 1917 and 1918, by uses.

	Percentage of total quantity.	Quantity (short tons).	Value.	Average price per ton.
1917.

Lime for all uses showed a decrease in 1918 except that used in tanning, metallurgy, and for miscellaneous or "other" uses. Building lime showed the greatest decrease in quantity sold. In this the figures bear out the statements of the manufacturers that the demand for building lime was greatly reduced owing to war restrictions. On the other hand, "other uses" showed an increase in quantity of 80 per cent. This division includes lime used in many industries greatly stimulated by the war demand, such as open-hearth steel furnaces, which use dead-burned dolomite as a refractory, and alkali and other works.

The greatest apparent decrease, about 23 per cent, was in the value of the lime sold to dealers, but some of this apparent decrease was in lime otherwise reported according to its ultimate use. The greatest increase in value was in lime sold for "other uses"—an increase of 108 per cent.

In 1918 Missouri, New York, and Pennsylvania supplied lime for all the uses listed, and Alabama, California, Indiana, Ohio, and Virginia for all but one of the uses. In 1917 Pennsylvania alone supplied lime for all the specified uses. This change was probably due in part to the fact that manufacturers were better able in 1918 to give information as to the uses for which their lime was sold and in part to the further fact that the decrease in demand for building lime compelled manufacturers to look to other industries in order to dispose of their product.

BUILDING.

Lime for building purposes showed a decrease of almost 400,000 tons, or about 30 per cent, in 1918. The quantities of building lime sold in each year have fluctuated considerably since 1907. The largest quantity reported for this use for any one year since 1907 was in 1909, when 1,906,146 tons were sold. Since 1916 the quantity sold yearly has on the whole decreased rapidly, although a considerable recovery was made in 1916. In 1917 the output of building lime represented 35 per cent of the total lime, but in 1918 it represented less than 29 per cent, and the value of building lime decreased about 11 per cent in 1918, compared with 1917. The average price per ton rose from $6.63 in 1917 to $8.51 in 1918—an advance of $1.88. In value building lime represented about 29 per cent of the total value.

It is needless to state that a recovery from this marked decrease is to be expected as soon as return to normal conditions removes the obstacles to building, and that the production of lime for building should increase steadily for at least a few years. This increase should be intensified by the increasing attention now being given to lime by producers, architects, and builders. As shown in figures 94 and 95, however, lime for building has been of decreasing importance in the lime industry for several years, and it is likely to be equaled or surpassed by that used in the combined chemical and manufacturing industries in the future, as it has been during the war.

Every State, with the exception of New York, Porto Rico, Rhode Island, and Washington, showed a decrease in the quantity of building lime sold in 1918. Ten States, however, showed an increase in value.

Manufacturers from all over the country reported the demand for building lime greatly decreased in 1918—a decrease due in large part to the war restrictions on building. Instability in business conditions caused individuals and communities to delay their building projects until a more favorable year. On the other hand, it is doubtful if a normal demand could have been met by the producers, who were greatly handicapped by lack of facilities. Ohio again led in the production of building lime, with Pennsylvania second, Wisconsin third, and Missouri fourth. Florida, Kansas, Oklahoma, and Wyoming were the only States whose total outputs went for building. These four States are small producers. The following table indicates the different ways in which building lime was used by consumers.

Building lime sold in 1918, classified by uses according to reports of the manufacturers.

Use.	Hydrated lime.		Quick lime.		Total.	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.	Quantity (short tons).	Value.
Plaster	178,811	$1,611,913	109,733	$888,214	288,544	$2,500,127
Mortar	32,219	271,685	59,004	471,484	91,223	743,169
Mortar and plaster	42,697	359,762	143,986	1,223,366	186,683	1,583,128
Unspecified	58,872	556,717	288,864	2,398,247	[a] 347,736	[a] 2,954,964
	312,599	2,800,077	601,587	4,981,311	914,186	7,781,388

[a] Includes 2,647 tons of lime, valued at $21,797, reported as sold for use in concrete, and 974 tons, valued at $6,096, reported as sold for use in gypsum products.

METALLURGY.

The lime used in metallurgy in 1918 amounted to 253,778 tons—an increase of 21 per cent over the quantity so used in 1917. The value of this lime was $1,884,672. In 1917 lime for metallurgy represented 5.5 per cent of the total production of lime; in 1918 it represented 7.9 per cent. The unusual increase in the production of this class of lime is easily accounted for by the greatly increased activity in the iron and steel industries because of the war, although part of the increase in production was probably due to the fact that some lime sold for metallurgic uses has been reported under "Chemicals" in previous years. Twenty-four States sold lime for metallurgy. Pennsylvania was the leading State, with West Virginia second and Missouri third. In the Rocky Mountain States and the Southwestern States a larger proportion of the total lime was sold for metallurgy than in any other section of the United States. More than half of the product from Colorado and Utah went for metallurgy. About one-fifth of the quantity of lime produced in each of these States—Arizona, Nevada, Missouri, and Washington—was used for metallurgy. In the other States less than 15 per cent of each State's total production was used in metallurgy. The average price per ton of this class of lime advanced from $5.44 in 1917 to $7.43 in 1918. The price in 1918 was 87 per cent higher than in 1916.

The following table shows that at least 51 per cent of the quantity of lime sold for metallurgic purposes in 1918 was used as blast-furnace flux and at least 18 per cent for the manufacture of steel. Much smaller quantities were used as smelter flux and for the manufacture of aluminum and brass.

Lime sold for metallurgic purposes in 1918, by uses.

	Quantity (short tons).	Value.
Blast-furnace flux	128,523	$903,574
Smelter flux	14,724	124,779
Manufacture of steel	44,544	342,917
Manufacture of aluminum and brass	18,292	140,393
Unspecified [a]	47,695	373,009
	253,778	1,884,672

[a] Includes some lime sold for metal pickling, and to smelters and furnaces for uses unspecified.

CHEMICAL WORKS.

Reports from a large number of manufacturers concerning trade conditions spoke of unusually good demands for chemical lime. It would therefore be expected that the output of chemical lime in 1918 would be much greater than in 1917. Only 566,532 short tons were reported as used in chemical works, however—an apparent decrease of 27 per cent from the quantity reported in 1917, and a corresponding decrease in value of 6.7 per cent. This apparent decrease was due to a change in statistical classification. In 1918 the Geological Survey for the first time added to the blanks sent out to the producers an itemized list of uses for lime included under the general heading "other uses." This caused producers to put in this section lime which they had in previous years considered as chemical lime, and accounts for the marked increase in lime for "other uses," which more than offsets the recorded decrease in lime for chemical uses. Figure 94 shows that from 1908 to 1917, inclusive, the quantity of lime sold yearly for chemical works has increased rapidly, except in the year 1914, when a slight decrease was noted. There was a sharp decrease in 1918, but the combined quantities of chemical and "other" lime show a substantial increase.

The average price per ton of chemical lime in 1918 was $7.37—an increase of 27 per cent over the price for 1917, and of 99 per cent over the price for 1916. Virginia, Michigan, Pennsylvania, and West Virginia, in the order named, were the greatest producers of chemical lime in 1918. Michigan's output of chemical lime was 82 per cent of its total output. South Dakota, Nevada, Vermont, Indiana, Virginia, and West Virginia were other States in which the production of chemical lime was a large percentage of the total output.

Lime reported as sold to chemical manufacturers in 1918.

Use.	Quantity (short tons).	Value.
Alkali works	145,031	$768,570
Potash salts	176	1,409
Ammonia works	13,975	99,831
Explosives (kind unspecified)	23,735	173,129
Nitrates and glycerin	2,059	12,468
Guncotton preparation and gelatin	10,755	88,784
Acids	38,388	298,660
Cyaniding	12,512	118,274
Calcium carbide	87,434	785,912
Alcohol:		
Dehydration and manufacture of	1,535	10,638
Wood distillation	13,986	121,678
Bleaching works	37,905	306,726
Phenol	25,002	196,463
Salt refining	1,791	13,388
Coal and water gas purification	171	1,959
Coke-oven by-products	24,451	174,437
Gas-plant by-products	2,371	19,309
Undistributed[a]	4,481	32,966
Unspecified	120,774	952,701
	566,532	4,177,302

[a] Includes lime sold for use in manufacture of calcium acetate, aluminum hydrate, barium products and precipitated calcium carbonate.

The above table shows the chemical uses for which manufacturers reported their lime sold in 1918. About 26 per cent of the chemical lime was used by alkali works. The manufacture of calcium carbide

consumed about 15 per cent and the manufacture of acids about 7 per cent. The use in bleaching also amounted to about 7 per cent of the total quantity. Other chemical uses required smaller quantities, although the manufacture of phenol, coke-oven by-products, alcohol, and explosives were important.

PAPER MILLS.

The quantity of lime sold to paper mills amounted to 325,172 short tons in 1918, 9 per cent less than in 1917, but its value, $2,610,645, was 30 per cent more than in 1917. The quantity of lime sold to paper mills has remained fairly constant since 1907, with the exception of the years 1914 and 1915, when there were decided decreases.

The average price per ton advanced to $8.03 in 1918—an increase of $2.38 over the price for 1917.

New England was the leading district in production of lime for paper mills, supplying 34 per cent of all the lime so used. Pennsylvania produced the greatest quantity in any single State, although lime for use in paper mills amounted to less than 10 per cent of its total production. Indiana, New York, and Wisconsin were also large producers of this class of lime.

According to data furnished by the lime manufacturers the following table shows how much lime was used for each of the paper processes. It will be noted that at least 46 per cent of the total quantity of lime for paper manufacture was used in the soda process, and that about 27 per cent was used in the sulphite process. Smaller quantities were used in the sulphate, strawboard, and rag processes.

Lime sold to paper mills in 1917 and 1918.

Manufacturing process.	1917		1918	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.
Soda	171,865	$994,417	149,443	$1,229,579
Sulphite	77,020	422,026	88,631	726,610
Sulphate	28,154	172,635	34,515	260,726
Strawboard	9,918	55,149	19,058	146,335
Rag	(a)	(a)	14,649	115,283
Unspecified	68,811	364,206	18,876	132,112
	355,768	2,008,433	325,172	2,610,645

a Included in "Unspecified."

In addition to these quantities of burned lime 101,305 short tons of raw limestone was sold to paper mills in 1917 and 100,247 short tons in 1918.

SUGAR FACTORIES.

The lime used in sugar factories in 1918 amounted to 36,494 tons in quantity and $314,748 in value. This was a decrease of 23 per cent in quantity and 18 per cent in value compared with the consumption in 1917. The quantity of lime used in sugar factories in 1917 was the greatest recorded since 1907.

The lime used in the sugar industry in the United States varies more in quantity than in any of the other uses classified here. In 1916 lime for this use showed a decrease of 36 per cent in quantity

and in 1917 an increase of 117 per cent. The average price per ton, $8.62, only advanced 59 cents beyond the price for 1917. Heretofore lime for use in sugar factories has had an average price per ton far above the normal price for the other uses, but in 1918 the average price per ton was only slightly above the price for all uses—$8.36.

Lime for use in sugar factories was burned in 14 States and in Hawaii and Porto Rico. California, as usual, was by far the greatest producer, its production, 17,254 tons, being 47 per cent of the total quantity consumed in the industry. Tennessee was also a large producer. In Hawaii 90 per cent of the total quantity of lime burned was used by sugar factories, and in Porto Rico about 50 per cent.

Some Pacific coast manufacturers have heretofore shipped their lime to Hawaii for use in the sugar factories there, but in 1918 that demand could not be met, as it was impossible to get the necessary transportation between the Pacific coast and Hawaii.

Both lime and carbon dioxide are used in the sugar industry, and many sugar manufacturers therefore prefer to quarry and burn their own limestone. The relation of lime to the sugar industry is more thoroughly illustrated by the following table, which shows that both limestone and lime decreased in about equal proportions:

Limestone and lime used by sugar factories, 1915–1918.

	1915		1916		1917		1918	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.	Quantity (short tons).	Value.	Quantity (short tons).	Value.
Limestone	394,122	$381,038	369,028	$369,694	530,612	$666,138	435,555	$649,589
Lime	34,025	230,368	21,923	118,572	47,546	381,746	36,494	314,748
	.....	611,406	.....	488,266	.....	1,047,884	.....	964,337

TANNERIES.

Lime used by tanneries amounted to 74,350 tons, valued at $637,960—an increase in quantity of 12 per cent and in value of 56 per cent, compared with 1917. The quantity consumed in 1918 for this purpose was greater than in any other year. The average price per ton increased from $6.14 in 1917 to $8.58 in 1918. Lime used by tanneries was produced in 19 States. Pennsylvania was by far the largest producer, having an output of 26,006 tons, or 35 per cent of the total quantity of lime used by tanneries. Vermont consumed 9,810 tons for this purpose, which was 27 per cent of the total quantity of lime produced by that State.

GLASS FACTORIES.

Lime used in glass factories in 1918 amounted to 34,051 tons, valued at $265,855. This represented 1.1 per cent of the total lime produced. The consumption in 1918 was a decrease in quantity of 26,573 tons, or 44 per cent, compared with 1917. In value this class of lime showed a decrease of 16 per cent. The increase in the manufacture of optical glass was very great in 1918, but the making of optical glass represents only a very small fraction of the

glass industry and calls annually for only a few carloads of lime, limestone, or marble, which must have a remarkably low content of iron (not more than 0.05 per cent). Many of the plants making window glass, plate glass, or bottle glass were shut down in 1918, and others were running on part time, principally because of failure to get priority orders from the Government for the shipment of coal. Ohio, Indiana, Pennsylvania, Missouri, Wisconsin, New York, and Arizona furnished the total production of lime for use in glass factories. Of this quantity Ohio furnished 28,633 tons, or about 84 per cent. Arizona and New York supplied only insignificant quantities.

The average price per ton of lime for glass works advanced from $5.22 in 1917 to $7.81 in 1918. Unburned limestome sold to glass factories amounted to 293,152 short tons, valued at $344,479, in 1917, and to 202,211 short tons, valued at $332,744, in 1918.

AGRICULTURE.

LIME AND LIMESTONE.

Twelve per cent of the total quantity of lime sold in 1918 was used for agriculture. This amounted to 391,047 tons, valued at $2,698,848, a decrease of 20 per cent in quantity compared with the output of 1917, but an increase of 9 per cent in value. This was the lowest yearly output of agricultural lime reported since 1908, the output of which had increased on the whole up to 1914, when 684,348 tons were produced. Since that time consumption for agricultural uses has declined at an increasing rate (figs. 94 and 95).

Agricultural lime was produced in 27 States and in Porto Rico in 1918. Pennsylvania led with a production of 200,073 tons, about 25 per cent of the total output of the State. The other leading States in order of production were: Maryland, Ohio, Virginia, and West Virginia. New Jersey's very small production was all used for agricultural purposes. Of Maryland's production 64 per cent was used in agriculture. The average price per ton of lime used in agriculture ($6.90) increased $1.83 over the price for 1917. Agricultural lime included 3,304 tons of lime, valued at $30,328, reported as sold for use in prepared fertilizer, and 1,989 tons valued at $6,750, sold combined with wood ashes.

Pulverized limestone for use in agriculture recovered from the slight decrease in 1917, and the quantity produced in 1918 was the largest yet recorded. The price per ton ($1.49) was 19 cents more than in 1917. The accelerated decline of agricultural burned lime in contrast to the almost steady increase of pulverized limestone during the last four years is rather discouraging to producers of burned lime. Both products have been given considerable publicity, and each possesses certain advantages. Scientific authorities have differed regarding some of these advantages, and some conclusions that were unfavorable to burned lime have been revised during the present year. The Lime Association has been calling attention to these revisions, and it will be interesting to see whether they result in a recovery from the decline in production of agricultural burned lime.

Lime and pulverized limestone sold for use in agriculture, 1911–1918.

Year.	Lime.		Limestone.	
	Quantity (short tons).	Value.	Quantity. (short tons).	Value.
1911	596,664	$1,714,386	174,290	$205,006
1912	604,607	1,852,530	200,000	311,702
1913	590,229	1,798,566	408,627	493,718
1914	684,348	2,139,444	615,197	688,961
1915	673,260	2,163,874	810,399	893,530
1916	613,527	2,224,401	1,066,376	1,146,582
1917	488,297	2,475,731	1,040,243	1,352,397
1918	391,047	2,698,848	1,091,918	1,626,292

CALCAREOUS MARL.

The calcareous marl industry, though still supplying only a small fraction of the total quantity of agricultural lime materials, has showed a marked increase during the last three years, as appears in the following table.

Calcareous marl sold in the United States, 1916–1918.

Year.	Quantity (short tons).	Value.	Average price per ton.
1916	58,088	$144,768	$2.49
1917	73,900	165,223	2.24
1918	98,694	261,082	2.65
Percentage of increase in 1918	33.6	58.0	.....

In 1916 and 1917 the entire output was reported as used in agriculture. In 1918 78,232 tons, valued at $203,500, was sold for use in agriculture, an increase of 4,332 tons (nearly 6 per cent) in quantity and of $38,277 (23 per cent) in value. The remaining 20,462 tons, valued at $57,582, was sold for the neutralization of acid waters, for use in making prepared fertilizers, and for other uses not specified.

Of the total marl produced 57,821 short tons, valued at $148,873, or $2.57 per ton, was fresh-water marl consisting mainly of small shells of fresh-water animals. It came from ten companies—six in Virginia, reporting a total output of 39,770 short tons, valued at $100,518, and one each in Arkansas, New York, Pennsylvania, and West Virginia.

The output of fresh-water marl in 1918 increased 21 per cent in quantity and 33 per cent in value, compared with that in 1917, which was 47,914 short tons, valued at $112,075, or $2.34 a ton, produced by nine companies—three in Virginia, two in California, and one each in New York, Pennsylvania, West Virginia, and Arkansas. The operations in Virginia in 1918 were at Barber, Alleghany County; Daleville, Botetourt County; Marlbrook and Riverside, Rockbridge County; and Claremont, Surry County. Two new companies at Claremont reported that shipments would be made in 1919. The plant at Caledonia, Livingston County, N. Y., which has been in operation for many years, was burned in 1917 and operations at the deposit have not been resumed, the marl sold in 1918 being

material on hand. A new company began operations at Cassadaga, Chautauqua County, N. Y. A plant has been erected and shipments are expected to begin in 1919. The Pennsylvania deposit is at Harmonsburg, Crawford County, and has been in operation three years. The West Virginia plant has been in operation two years and is at Charles Town, Jefferson County. No sales were reported in 1918 from the deposits near San Jose, Santa Clara County, and Lemon Cove, Tulare County, Calif. In Arkansas the material reported is chalk and the deposit is at White Cliff, Little River County.

Marine marl, derived from fragments of the shells of marine animals, was produced in 1918 at five deposits in the Coastal Plain region of North Carolina and South Carolina. The output amounted to 40,873 short tons, valued at $112,209, or $2.75 a ton, compared with 25,986 tons, valued at $53,148, or $2.05 a ton, in 1917, an increase of 14,887 tons (57 per cent) in quantity and $59,061 (111 per cent) in value. These deposits are near Charleston, S. C., and near Newbern, Craven County, and Pollocksville, Jones County, N. C.

DEALERS.

Lime sold to dealers in 1918 constituted only 3.5 per cent of the total sold and showed a decrease of 43 per cent in comparison with the sales to dealers in 1917. This large decrease was probably due to the same causes as the decrease in 1917—much better knowledge of the ultimate uses of the lime and a larger percentage of the quantity going directly to the consumer.

OTHER USES.

Under "other uses" is included lime for at least 30 different purposes that can not properly be classified with the principal uses already named. The total lime sold for "other uses" in 1918 amounted to 499,063 tons in quantity and $5,476,895 in value—an increase compared with 1917 of 80 per cent in quantity and 108 per cent in value. In 1917 lime for "other uses" made up only 7.3 per cent of the total quantity, but in 1918 it made up about 15.6 per cent.

The quantity of lime sold for "other uses" increased steadily from 1908 to 1916 (fig. 94). In 1916 lime for metallurgy was made a separate item. This caused a marked decrease in the quantity of lime still recorded under "other uses" (fig. 95). In 1917 lime for glass works was made a separate item, and this caused another decrease. Notwithstanding the fact that two important items were taken out and put into separate classes, the quantity of lime for "other uses" in 1918 was by far the largest yet recorded. The average price advanced from $9.52 in 1917 to $10.97 in 1918.

Lime for refractories, almost all of which was dead-burned dolomite, made up about 64 per cent of all the lime sold for "other uses." Four States (Pennsylvania, Ohio, New York, and Indiana) produced all the dead-burned dolomite in 1918. Pennsylvania and Ohio together produced 295,737 tons. Part of the dead-burned dolomite credited to Ohio was quarried in Ohio, but burned in West Virginia. Besides the quantity here recorded, which was burned by the producers, 490,863 short tons of raw dolomite, valued at $560,209,

was sold for this purpose by producers of stone. Dead-burned dolomite has been extensively used to replace Austrian magnesite for maintaining the bottoms and lining the walls of open-hearth and electric furnaces. Its future depends largely on the extent to which it can compete with domestic and foreign magnesite when normal conditions are again restored. The total quantity sold in 1917, including the dead-burned equivalent of the raw dolomite just mentioned, exceeded the combined quantity of domestic and imported magnesite (figured as the calcined product) sold in that year. The total quantity sold in 1918 showed a substantial increase over that in 1917, although several other refractories and metallurgical products decreased. These facts indicate a wider use than was formerly supplied by magnesite, and imply that although it owes its prominence to war conditions it is likely to retain its importance.

About 15 per cent of lime for "other uses" was used for water purification and softening. The remaining 21 per cent is itemized in the following table:

Lime sold for "other uses" in 1918.

Use.	Quantity (short tons).	Value.
Refractories	318,896	$4,097,819
Silica brick	26,517	182,659
Sand-lime brick	7,417	59,357
Soap	29,599	202,028
Lubricating grease, renovating of butter, etc	3,395	28,410
Kalsomine	999	9,076
Water purification and softening	75,148	596,667
Sewage purification and neutralization of acid water	9,514	68,668
Disinfectants	6,059	51,438
Glue manufacture	8,822	78,599
Pottery and porcelain manufacture	129	1,213
Polishing and buffing compounds	384	4,424
Cotton, thread and woolen mills	2,117	21,425
Flour mills	164	1,785
Spraying	1,813	16,706
Undistributed[a]	7,790	56,621
	499,063	5,476,895

[a] Includes small quantities of lime reported as sold for manufacture of candles, corn products, dyes, rubber, proprietary medicines, varnish, graphite, for refining gold and platinum, for use in slag cement, in print works, tobacco factories, copper and file works, for sheep dip, and other uses not specified.

During 1918 the Lime Association, through its chemical bureau, began a systematic study of the many chemical uses of lime. The work has thus far disclosed a surprising lack of regard on the part of chemists in manufacturing plants for the properties and purity of lime. It is expected that more care, in at least some of the uses of lime listed above and on page 835, will lead to an increased appreciation of lime as a chemical reagent and to a consequent increased demand for it. This first appearance of these tables is therefore timely and will also serve as a guide to manufacturers in efforts to increase their range of markets.

HYDRATED LIME.

The production of hydrated lime, like that of quicklime, was considerably reduced in 1918, but the decrease in quicklime amounted to 16 per cent, whereas the decrease in hydrated lime amounted to only 12.5 per cent. This decrease followed a slight decrease in 1917, which was the first since the slight decrease in 1911. The greatest production of hydrated lime was recorded in 1916 and amounted to 717,382 tons. In value the hydrated lime production of 1918 was an increase of $699,109, or 15 per cent, compared with that of 1917, and was by far the largest ever recorded. The value of hydrated lime has increased continuously and rapidly ever since 1908 (Pl. VII). The average price per ton increased from $6.55 in 1917 to $8.61 in 1918. From 1906 up to and including 1915 the price has fluctuated between $4 and $4.50, but since 1915 there has been a steady increase. The price in 1918 was an increase of 104 per cent over the price of 1915. The production of hydrated lime made up 19 per cent of the total quantity of lime produced in the United States in 1918.

Hydrated lime manufactured and sold in the United States, 1906–1918.

Year.	Quantity (short tons).	Value.	Average price per ton.	Number of plants reporting operations.
1906	120,357	$479,079	$3.98	30
1907	140,135	657,636	4.69	33
1908	136,411	548,262	4.02	46
1909	204,611	904,900	4.43	50
1910	320,819	1,288,789	4.02	51
1911	304,593	1,372,057	4.50	60
1912	416,890	1,829,064	4.39	64
1913	493,269	2,205,657	4.47	80
1914	515,121	2,239,916	4.35	82
1915	581,114	2,457,602	4.23	84
1916	717,382	3,626,998	5.06	89
1917	709,157	4,643,004	6.55	90
1918	620,216	5,342,113	8.61	90

Ninety hydrated-lime plants were in operation in this country in 1918, the same number as in 1917. These plants were distributed in 25 States. Hawaii was added to the list of hydrated-lime producers in 1918. A decrease in the number of plants operating was noted in California, Illinois, Maryland, New York, Virginia, Washington, and West Virginia, each of which lost one plant. On the other hand, Massachusetts increased its number of plants from 1 to 3, Pennsylvania from 13 to 16, and Wisconsin from 2 to 3.

Lime-hydrating plants in operation in 1909–1918.

As only 11 States had three or more companies operating hydrating plants in 1918, the totals of the other States could not be published without revealing individual figures. The following table is therefore very incomplete:

Hydrated lime sold in the United States in 1917 and 1918.

State.	1917		1918	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.

a Included in "Undistributed."

Ohio was again the leading producer of hydrated lime, and Pennsylvania was second. Both of these States showed decreases in quantity but increases in value. In Ohio the quantity decreased 26 per cent and in Pennsylvania 6 per cent. In Indiana, Maryland, Missouri, Tennessee, and Texas, however, there was an increase in the quantity as well as the value of hydrated lime produced.

Hydrated lime for building constituted 50 per cent of the total hydrated lime. There was a decrease of 89,624 tons, or 22 per cent, compared with the hydrated lime consumed for building in 1917. The value, however, increased 4 per cent.

A large quantity of hydrated lime (29 per cent of the total) was also used for agricultural purposes. This class of lime increased slightly in quantity. The increase in value amounted to 30 per cent.

The decrease in the use of hydrated lime for chemical purposes was very marked, even the value in this case being lower for 1918 than for 1917. There was a marked increase, however, in hydrated lime for "other uses," even more than for quicklime for that purpose. This increase was undoubtedly due to the same cause as the increase in quantity of quicklime for this purpose—the more detailed classification under "other uses" and the inclusion under that head of lime which in 1917 would have been included under chemical lime. The hydrated lime sold to glassworks dropped from 2,827 tons in 1917 to to 922 tons in 1918.

Although quicklime sold to dealers showed a very marked decrease, hydrated lime showed an increase of 1,925 tons, or 6 per cent, in quantity and an increase of 46 per cent in value.

Hydrated lime sold in the United States in 1917 and 1918, by uses.

Use.	1917		1918

CONSUMPTION.

In considering any table giving figures on consumption of lime by States it must be remembered that the relation of production to consumption is governed by many factors—the presence of large workable deposits of limestone within a State and the distance of that State from States without such deposits; the availability of transportation lines from the State; the presence of large centers of population in a State and their proximity to limestone deposits in the same State or in other States. Small quantities of lime, of an exceptional grade, may be shipped long distances for special purposes.

Lime consumed in the United States in 1918, in short tons.

State.	Production.	Shipments from State.	Shipments into State.	Consumption.					Population in 1918 (estimated).
				Quicklime.	Hydrated lime.	Total lime.	Per capita (estimated).

a Included in "Undistributed."
b Includes 516 tons shipped to Mexico, 33 tons shipped to South America, and 12,108 tons shipped to Canada.

Production exceeded consumption in 15 States. Of these States Indiana, Massachusetts, Missouri, Ohio, Pennsylvania, Tennessee, Virginia, and West Virginia were large producers. Some States produce large quantities of lime for which there is little demand within the State and ship this lime to neighboring States. Such a State is Alabama, which ships most of its lime to Georgia, Mississippi, Louisiana, and South Carolina.

In three of the New England States—Vermont, Massachusetts, and Connecticut—production exceeded consumption. A great part of the product from these States was shipped to other New England States and to New York. Small quantities went to Pennsylvania, Ohio, and Canada. New Hampshire produced no lime, but consumed about 34,000 tons. Shipments into New England States came principally from other New England States and from New York with smaller quantities from Pennsylvania, Ohio, Maryland, and Missouri.

New York consumed more than twice as much as it produced. It made shipments of small quantities to 18 States and Canada, but it received large quantities from Ohio, Pennsylvania, Massachusetts, Maine, and West Virginia, and small lots from Southern and Central States. Pennsylvania, although the largest producer, consumed almost as much as it produced. This State shipped to 23 other States and to Canada, the largest quantities going to New Jersey, New York, Maryland, Delaware, and Ohio. Shipments into Pennsylvania came from Maryland, Ohio, New York, Virginia, and West Virginia. Pennsylvania consumed more than three times as much as any other State except Ohio.

All of New Jersey's production was used for home consumption. In addition, this State received lime from nine States, including Pennsylvania, Ohio, Maryland, Massachusetts, and New York.

Delaware produced no lime, but consumed about 53,000 tons, and, as usual, led all States in consumption of lime per capita.

Among the Southern States there were four in which production was far greater than consumption—Virginia, West Virginia, Tennessee, and Alabama—and five in which consumption greatly exceeded production—Kentucky, North Carolina, South Carolina, Georgia, and Florida. Although Virginia was the greatest consumer among the Southern States, its production exceeded its consumption, and it made large shipments to Maryland, North Carolina, Pennsylvania, New Jersey, and New York. The States in this section that consumed large quantities obtained their lime from the other Southern States and from Ohio and Maryland, while the large producers in the South supplied the other Southern States and also Pennsylvania, Ohio, and Maryland.

The section which includes Ohio, Indiana, Illinois, Michigan, and Wisconsin produced 29 per cent of the total quantity of lime produced in the United States. In these States there are a great many workable limestone deposits, but there are also many large industrial centers, and therefore this section consumes almost as much as it produces. Ohio produced in 1918 much more than it consumed and shipped to 32 States and to Canada. Illinois, on the other hand, consumed twice as much as it produced, and received lime in large quantities from Missouri, Wisconsin, Ohio, and Indiana. Indiana produced slightly more than it consumed. Its principal shipments were made to Illinois, Kentucky, Ohio, Michigan, and Wisconsin. A small quantity was shipped to Canada. Michigan consumed more than it produced. It shipped lime to only three States—Indiana, Minnesota, and Wisconsin—but it received large quantities from Ohio, West Virginia, Indiana, and other States. Wisconsin also consumed slightly more than it produced.

Missouri supplied a large quantity of the lime for other States, for while its production was 201,737 tons, its consumption was only 62,601 tons, less than one-third of the production. It made shipments to 29 States, Canada, and Mexico, the largest quantities going to Illinois, Wisconsin, Kansas, Oklahoma, and Iowa.

Iowa, Kansas, Minnesota, North Dakota, South Dakota, and Nebraska all consumed more than they produced. North Dakota and Nebraska had no production. A great part of the lime shipped into the States of this section came from Missouri, although Wisconsin, Ohio, and Illinois also supplied considerable quantities.

Although Louisiana had no production, it consumed 27,340 tons, this quantity coming principally from Alabama, Tennessee, Texas, and Missouri.

Both production and consumption amounted to very little in Arkansas and New Mexico. In Oklahoma consumption greatly exceeded production. Oklahoma shipped lime outside the State to Texas only, but it received shipments from Texas, Missouri, and Arkansas, and a small quantity from Ohio.

Production exceeded consumption in Texas by 16,205 tons. This surplus was shipped in great part to other Southwestern States.

Production in the Rocky Mountain States—Montana, Wyoming, Colorado, and Utah—amounted to 19,156 tons, but consumption in these States exceeded this quantity by 11,301 tons. This excess consumed came principally from Missouri and Washington, with small quantities from several other Western States, as well as from Illinois and Pennsylvania.

Arizona produced 11,212 tons, of which more than half was shipped out of the State, practically all to California. A few thousand tons were received from Texas and a very small quantity from California.

Both consumption and production were small in Idaho, Nevada, and Oregon, but consumption exceeded production. Lime was received in these States from California, Washington, and Alabama. The whole quantity received from Alabama was hydrated lime. Small shipments were received from other Western States.

California consumed a little more lime than it produced. It made small shipments to Arizona, Nevada, and Oregon and received fairly large quantities from Arizona and Nevada and small quantities from Washington and Ohio, besides imports from British Columbia.

Washington produced 6,981 tons more than it consumed. Lime shipped out of the State amounted to 8,257 tons. Oregon received a large part of these shipments, and other Pacific Coast and Rocky Mountain States and Canada received smaller portions. A small shipment was made to Hawaii.

Canada received 12,108 tons of lime from the United States, more than half of this coming from New York State. Eight other States —Indiana, Michigan, Missouri, Ohio, Pennsylvania, Vermont, Washington, and West Virginia—supplied smaller quantities.

Only 516 tons was shipped to Mexico, all of it furnished by Arizona, Missouri, and Ohio.

A comparison of the rank of States by production and by consumption shows some interesting facts, although it must be borne in mind that because a State has a higher rank in production than it has in consumption it does not necessarily mean that the State's actual

production exceeded its actual consumption; sometimes the reverse is true.

Pennsylvania and Ohio were first and second, respectively, in both consumption and production, but New York, which was third in consumption, was twelfth in production. In spite of New York's rather abundant deposits of limestone, its principal centers of consumption are most readily supplied from adjacent States. Illinois was sixth in consumption but fourteenth in production, its principal consuming district, Chicago, being readily supplied from plants on the Great Lakes, and its southern part being most readily supplied from Missouri. New Jersey, which consumed all the lime produced in the State and imported large quantities from conveniently situated districts and districts producing certain grades of lime, was ninth in consumption and thirty-seventh in production. Delaware, which contains no deposits of limestone, received such large quantities of lime from other States that it took fifteenth place in consumption. North Carolina was sixteenth in consumption, but twenty-seventh in production, as its active kilns are situated in its western part more convenient to cities in South Carolina than to several of its own important cities, and as its demands are largely for higher calcium lime than it has heretofore produced. Kansas for the same general reasons was twenty-sixth in consumption but fortieth in production.

On the other hand, Missouri was fourth in production but sold so much of its lime outside the State that it was only fourteenth in consumption. The conditions were about the same in West Virginia, for it was fifth in production but twentieth in consumption.

CONSUMPTION PER CAPITA.

In 1918 the average consumption of lime per capita decreased to 0.030 short ton, compared with 0.037 short ton in 1917 and 0.040 short ton in 1916. Delaware again had the highest per capita consumption, which increased from 0.19 to 0.245 ton. The district surrounding Delaware, including Maryland, Virginia, and Pennsylvania, also showed a very high per capita consumption, though less than in 1917, because of the marked decrease for building, agricultural, and certain chemical uses. New Jersey and the District of Columbia continued to maintain about the average rate of the country, but Massachusetts and Connecticut declined somewhat further below the average than they did in 1917. Similar relative declines, as was to be expected, characterized all sections of the country. The only State besides Delaware with relatively high per capita consumption to show increase was New Hampshire. Tennessee, Montana, and Arizona increased their small rates. Porto Rico, North Dakota, and Alaska had the lowest per capita consumption.

IMPORTS.

Imports have varied considerably in the last few years, although neither the quantity nor the value have reached the figures for 1909. The imports for 1918 decreased 9.6 per cent in quantity but increased 4 per cent in value as compared with 1917.

Lime imported and entered for consumption in the United States, 1909–1918.[a]

Year.	Quantity (short tons).	Value.	Year.	Quantity (short tons).	Value.
1909	8,687	$75,556	1914	3,455	$33,670
1910	6,498	63,791	1915	1,956	22,489
1911	5,232	55,255	1916	7,959	71,663
1912	4,268	48,153	1917	7,353	70,505
1913	4,139	48,538	1918	6,650	73,458

[a] Most of the lime imported into the United States comes from Canada.

EXPORTS.

Exports of lime, as shown in the following table, decreased in quantity as well as in value in 1918. They represent 0.2 per cent of the quantity marketed, compared with 0.5 per cent in 1917.

Lime exported from the United States, 1913–1918.

Year.	Quantity (short tons).	Value.	Average price per ton.	Year.	Quantity (short tons).	Value.	Average price per ton.
1913	29,475	$212,345	$7.20	1916	23,973	$132,769	$5.54
1914	24,141	170,744	7.07	1917	18,794	168,671	8.97
1915	16,223	106,312	6.55	1918	7,191	105,803	14.71

The statistics in the following table were compiled from records of the Bureau of Foreign and Domestic Commerce, United States Department of Commerce:

137536°—M R 1918—PT 2——54

Lime exported from the United States, 1917–1918.

	18,794	168,671	7,191	105,803

(a) Less than 1 ton.

A discrepancy will be noted between the figures for consumption, in which shipments to Canada amount to 12,108 tons, and the figures for export, in which shipments to Canada amount to only 5,337 tons. The consumption figures are gathered from shipment statements of manufacturers and the export figures are collected by United States agents at the ports. Part of the discrepancy is no doubt due to the fact that shipments of lime to foreign countries are often consigned at the plant before the end of the year, but do not leave the port for foreign shores until after the beginning of the following year. It often happens, too, that shipments of lime designated for foreign countries at the plant are diverted by agents to destinations within the United States before they reach the ports.

FUELS.

The following table shows the distribution by States of kilns using various kinds of fuels. The total number of kilns decreased about 20 per cent in 1918, as compared with 1917. The kilns using coal decreased 22 per cent, from 1,138 in 1917 to 885 in 1918. The number of kilns using coal increased from 31 to 34 in Indiana, from 26 to 36 in Maryland, from 24 to 29 in Missouri, and from 14 to 17 in

Texas, but the number decreased from 280 to 174 in Ohio, from 502 to 400 in Pennsylvania, and from 42 to 27 in Tennessee. Less marked variations occurred in other States. The decrease in the number of kilns using wood in 1918 amounted to 28 per cent. The greatest decreases occurred in States where wood was largely used—Florida, Maine, Missouri, New York, and Wisconsin. The number of wood-burning kilns in Wisconsin decreased from 72 to 34. The number of wood-burning kilns increased in Porto Rico from 16 to 25, in Pennsylvania from none to 7, and in Tennessee from 1 to 9.

The number of kilns burning oil decreased from 27 in 1917 to 24 in 1918. Only three States used oil-burning kilns—California, Hawaii, and Nevada. Kilns using natural gas were reported only from Ohio and Pennsylvania in 1918 and showed a decrease from 25 in 1917 to 21 in 1918. Producer gas was used in kilns in 12 States, the largest number being found in Ohio, Michigan, and Pennsylvania. The number of kilns using this fuel decreased 12 per cent in 1918. The greatest number of coke-fired kilns are found in Pennsylvania, Maryland, West Virginia, and Virginia. These decreased about 20 per cent in 1918. Kilns burning a mixture of coal and wood were used in 17 States, particularly Missouri, Alabama, Pennsylvania, Connecticut, and Massachusetts, and the number in use in 1918 remained the same as for 1917. Kilns burning mixed coal and coke were used in only three States in 1918—Maryland, Pennsylvania, and Virginia, and this number decreased from 51 in 1917 to 37 in 1918.

At least five companies used lignite as fuel in 1918. This has been included under coal in the table showing the various kinds of fuel used.

One producer reports that lignite compares favorably with other fuels, both in cost and the quality of lime produced. A lignite containing a large percentage of moisture produces a soft-burned lime similar to lime burned with wood. It usually requires about half a ton of lignite to burn a ton of lime. If lignite is to be used efficiently, it should be burned in a kiln having a fire box with large grate area and a high arch or combustion chamber. The kiln should also have a taller shaft than usual since the gases in lignite distill off very rapidly. Unless a high arch in combustion chamber and a tall shaft for the kiln are used the gases will burn on top of the kiln. Lignite can not be stored but must be used fresh. After storing lignite a week or two it will produce only about half the quantity of lime it does when used fresh.[1]

[1] Remarks on lignite from personal communication of H. Dittlinger to G. F. Loughlin.

[a] Includes a small percentage of kilns burning unspecified mixtures of fuels.

KILNS.

The following definitions of the different types of limekilns are those suggested by W. E. Emley: [1]

A "field" kiln is distinguished from all other types by being intermittent in its operation. Firing is continued until the contents of the kiln are calcined, when the kiln is entirely emptied. Under some conditions it may be demolished and rebuilt after each burn. A "continuous" kiln is a kiln of any type other than a field kiln.

A "pot" kiln is a vertical shaft kiln which is continuous in its operation. Its peculiar characteristic is that the fuel and stone are charged into the kiln in alternate layers.

A "flame" kiln is a vertical shaft kiln which is continuous in its operation. Its name is derived from the fact that only the flame of the fuel and not the fuel itself comes into contact with the stone or lime. This type is sometimes known as a "patent" kiln, but the term "flame" is to be preferred as more significant.

The total number of kilns in use decreased about 20 per cent in 1918. All types of kilns showed a decrease with the exception of rotary kilns, which increased 42 per cent. In 1917 there were 19 rotary kilns in use; in 1918 there were 27. The fact that the number of rotary kilns increased despite the decrease in the total number of kilns in use would seem to indicate that the rotary kilns are beginning to be recognized as a very efficient type, not so much for their best economy as for their ability to burn smaller sizes of stone, which choke the draft in upright kilns, and to produce a good quality of lime, especially for hydrating plants.

As a part of the work of the Air Nitrates Corporation, financed by the Government, a lime plant was built at Muscle Shoals, Ala., in 1918, that was equipped with seven rotary kilns, each 8 by 125 feet.

CLAY-WORKING INDUSTRIES.[1]

By Jefferson Middleton.

GENERAL CONDITIONS.

This report deals with the products of the clay-working industries as well as with clay mining, and the tables are made up to show the output in their first form of manufactured clay products as best expressing the production of clay.

The year 1918 was one of unusual conditions in the clay-working industries. The country was at war, and structural work, which normally consumes more than a third of the output of clay products, was restricted to the needs of the Government and essential war industries. Under these conditions all clay products except refractories and pottery (taken as a whole) decreased in value, compared with 1917.

The value of clay structural materials in 1918 was $66,209,300, a decrease of $19,450,587, or 23 per cent, compared with 1917. The clay products used chiefly in engineering works—vitrified paving brick or block, sewer pipe, and draintile—were valued at $30,675,231 in 1918, a decrease of $8,304,703, or 21 per cent. The refractories—fire brick, including special shapes, and stove lining—were valued at $52,726,249, an increase of $9,130,985, or 21 per cent. No statistics are collected to show the quantity of stove lining marketed, but it seems quite probable that the increase in value in 1918 was caused by the increase in price rather than in output. Pottery products (valued at $65,222,951) also increased in value by $9,060,429, or 16 per cent. As the selling price of clay products per unit was much higher in 1918 than in 1917, the quantity of material, even where the value increased, was much less than in 1917. Notwithstanding the increase in value of refractories and pottery the net decrease in value of clay products in 1918 compared with 1917 was $10,628,122, or nearly 5 per cent. The total value of the clay products marketed in 1918 was $221,884,651.

The causes for these changes are not far to seek. In general the high cost and scarcity of materials, the uncertainty of labor, and unfavorable transportation conditions tended to curtail production. The decline in the demand for structural materials was felt early in the year on account of the decline in general building. Vitrified paving brick, sewer pipe, and draintile, used principally in engineering works, should have apparently been in strong demand for roads and public utilities in Army camps and cantonments, but war conditions and Government restrictions caused the output to decrease.

[1] Tables of production were prepared by Miss Belle Worth Bagley and Miss Katrine W. Cottrell, and tables of imports and exports by J. A. Dorsey.

The increase in refractories was due to the demand for them in the manufacture of iron and steel and allied industries. The large increase in the value of pottery was due to increased price rather than to increased output, though the potters were at times almost swamped with orders.

For some years silica fire brick were included with clay fire brick. Until 1916 their production and value were comparatively small and were not important factors in the total. Since 1915, however, the value of silica brick has increased so rapidly that it has been thought best to exclude silica brick from the table of clay products and to present the statistics concerning them in a separate statement.

The imports of clay products, 96 to 98 per cent of which have usually been pottery, showed in 1918 an increase of $41,627, or less than 1 per cent, compared with 1917. This increase was in pottery ($60,266), imports of brick and tile decreasing $18,639. Owing to the unusual demand at home, however, this slight increase had no apparent effect on the domestic production of pottery, the proportion of which to consumption was 93 per cent, the highest recorded.

The exportation of clay products, a comparatively unimportant but growing factor in the industries, showed another large increase in 1918 and reached the maximum value, $7,932,574, which was $979,311, or 14 per cent, greater than in 1917. Fire brick continues to be the principal clay product exported, its value in 1918 constituting 63 per cent of all exports. Canada is the best foreign market for clay products exported from the United States, 60 per cent of our exports going to that country in 1918.

In their statements to the Geological Survey the producers report quantities for common brick, face brick, vitrified brick or block, hollow building tile, and fire brick, but not for fancy brick or for enameled brick. The average price per thousand for these varieties increased as follows: Common brick from $8.17 to $10.90, vitrified brick or block from $15.09 to $17.74, and fire brick from $32.59 to $42.25. These advances seem no more than reasonable, except possibly in fire brick, compared with the increase in the cost of labor and materials. Only one variety of brick and tile, fire brick, reached its maximum value in 1918. No product reached its maximum output, so far as can be determined, as common brick, face brick, and vitrified brick or block each showed a large decrease in quantity.

The number of firms reporting sales continues to decrease, the number for 1918 being the smallest in the history of the industry and less than half of the maximum number reported for 1899. The decrease, which has been a steady one for many years, is caused principally by the elimination of the smaller plants, which is ascribed to the encroachment of cement or concrete and to the consolidation of plants for more efficient management. Undoubtedly, however, many plants were idle and made no sales of products in 1918—a condition which caused an additional decrease in the number reporting sales. The increase in the size of the operations is shown by the increase in the average value per active operator reporting, which increased from $13,760 in 1899 to $79,729 in 1918. The number of operators does not indicate the number of plants, as one operator may have more than one plant—in fact, some operators have a dozen or more. Clay products, except the highest grades, are made for local consumption, their low value permitting transportation for any considerable distances. Hence local conditions, including weather, seriously affect

some branches of the clay-working industries. Imports consist chiefly of the highest grades of ware, principally pottery, and the European war, until this country entered it, had little direct effect on the brick and tile industries. Some of these wares, however, have been made from imported clays, especially from the high-grade English and German clays, and the decrease in the imports of the German clay has affected the manufacture of crucibles, lead pencils, and glasshouse pots, though domestic clays were being successfully used in 1918 in the manufacture of these wares to a greater extent than ever before.

The draft on labor for military purposes was not sufficient to cause any considerable introduction of female labor into the clay-working industries. Women were employed in the manufacturing phases of the industry at two brick and tile plants.[1] In the pottery industry little or no replacement of men by women took place, though had hostilities continued resort to such replacement on a large scale would have been necessary.

The immediate effect of the conditions prevailing in 1918 was of course the hampering of the industries. The ultimate effect, however, will be beneficial, as the necessity of economy in the production of wares was brought home to the operators as never before. The great impetus given to the development of improved kilns, designed to save time and fuel and labor, and the realization that machinery must play even a more important part in these industries in the future than in the past will be the principal benefits. The standardization both of refractory brick and of shapes inaugurated by Dr. Charles Catlett, of the War Industries Board, and the elimination of many patterns of pottery should also be beneficial.

FUEL RESTRICTIONS.

The clay-working industries were also subject to curtailment of fuel and to building and other restrictions imposed by the war boards with a view to making the country more efficient in the supreme business of the times, that of winning the war. The fuel curtailment order issued by the Fuel Administration to the clay-working industries under date of April 13, 1918, provided that the percentage of fuel allowed for these industries, as compared with that shown by the average consumption in 1915, 1916, and 1917, would be 50 per cent for common brick, paving brick, face brick, terra cotta, roofing tile, floor and wall tile, and sanitary ware; 75 per cent for hollow tile, sewer pipe, drain tile and flue lining; and 85 per cent for stoneware, except chemical stoneware.

By the courtesy of the Bureau of Statistics of the United States Fuel Administration the Geological Survey is enabled to publish the following table, which shows by States the quantity of coal consumed in the clay-working industries. These figures apparently do not include the pottery industry, except the manufacturers of stoneware and sanitary ware. The Fuel Administration had the following to say concerning the saving of coal by reason of its curtailment orders:[2]

Official reports from the clay-product industries, covering the first six months of 1918, showed a saving of 1,846,996 tons of coal resulting from the orders issued by the

[1] Brick and Clay Record, vol. 52, No. 4, Feb. 12, 1918.
[2] Fuel Facts, 2d ed. (revised), p. 46, December, 1918.

Fuel Administration restricting the amount of fuel to be used by plants in this industrial group. The restrictive orders were made necessary in order that essential war activities might not suffer for an adequate supply of fuel. * * *

Present reports indicate that under the orders curtailing the fuel supply of this industry, which became effective April 13th last, there was effected 37 per cent reduction in the normal amount of coal consumed.

The figures announced are of particular interest, inasmuch as the curtailment orders were so worded that plants were permitted to burn their allotment of fuel at any time during the year, and many concerns chose to operate at full capacity until their fuel allowance was consumed, and then close down entirely. It is apparent, therefore, that had the war continued and the necessity for curtailment remained, the figures for the last half of the year would have revealed a very much greater saving. [Final figures, as shown by the table, estimate the saving at 4,000,000 tons.]

CLAY AGGREGATE FOR CONCRETE SHIPS.

One of the most interesting and perhaps important developments of the year was the experiment of building seagoing ships of concrete. In order to make the concrete as light in weight as possible, various light-weight materials including slag, volcanic scoria, and pumice were tried. An aggregate made of burnt clay was found to be the best substitute for stone and gravel in concrete, and its use reduced the weight of the concrete from 150 to 118 pounds per cubic foot. Burnt-clay aggregate in concrete has been used only in shipbuilding, but from the tests of the material in connection with that work there seems to be no reason to suppose that the light-weight aggregate may not find other uses where the weight of ordinary concrete is an objection, as in floors, roofs, and cars.

The following account of the development of this material, including tests of the compressive strength, permeability and absorptive properties of concrete made with clay aggregate, is taken from the Engineering News-Record of April 24, 1919:

HISTORY AND PROPERTIES OF LIGHT-WEIGHT AGGREGATES.

BURNT CLAY OR SHALE, PRODUCING MATERIAL FULL OF NONCONNECTING CELLS AND MAKING CONCRETE OF HIGH STRENGTH AND LIGHT WEIGHT, DEVELOPED BY GOVERNMENT'S CONCRETE-SHIP ENGINEERS.

Light-weight aggregate made from an artificially burnt shale or clay is now being used for the concrete on all of the Government concrete ships. The concrete so made, in rich mixtures and with a fine-ground cement, weighs from 100 to 118 pounds per cubic foot, and tests in compression from 3,500 to 5,500 pounds per square inch at the end of 28 days. Furthermore, it is impermeable, readily workable, and, so far as has been ascertained, has no defects not common to concrete with any of the more generally used aggregates. This artificial aggregate has been developed by the concrete ship section of the United States Emergency Fleet Corporation, but until now no definite statement of its method of manufacture or of its properties has been given out. Engineering News-Record is permitted here to make public the present knowledge of the material.

Early in the study of the concrete ship it became evident that to compete commercially with wood and steel the concrete must be lighter than the 150 pounds per cubic foot structural mixture commonly used. Naturally, low-weight concrete meant a low-weight aggregate. Many investigations were made into the possibilities of slag and various light, natural aggregates, such as volcanic scoria, pumice, etc., all of which are of a vesicular nature, that is, full of small nonconnecting cells, which reduce weight. In pursuance of these studies it was found that certain clays or shales could be burnt so as to produce a light-weight vesicular product similar in appearance

and qualities to the volcanic basalts, but more uniform in character and therefore better fitted for aggregates.

Accordingly, experimental work was started at the Bureau of Standards in the early summer of 1918 on quantity production of this material. The first working plant was a down-draft beehive kiln near Birmingham, Ala., where enough aggregate was turned out to supply the 3,000-ton *Atlantus* launched in December at Brunswick, Ga. Experiments were also carried on in a Portland cement rotary kiln at Ragland, Ala., and initiated at a railroad tunnel kiln at Perth Amboy, N. J., local clays and shales being used at each, but neither progressed beyond the experimental stage. Later, however, two contracts were let for quantity production for the big concrete ships under way; one to the Atlas Portland Cement Co., which makes the aggregate in cement kilns at Hannibal, Mo., and one to the Los Angeles Pressed Brick Co., which made the aggregate in dome kilns formerly used for burning brick. Both plants are now producing aggregates, the Hannibal plant supplying the ships at Wilmington, N. C., Jacksonville, Fla., and Mobile, Ala., and the Los Angeles kilns those at San Diego and San Francisco. In all, 25,000 tons of the aggregate will be required for the present Government program.

The new light-weight aggregate, as has been stated, is an artificially burned clay or shale uniformly filled with small nonconnecting cells. Speaking nontechnically it is a bloated brick, that is, the basic clay or shale from which it is formed, when subjected to a temperature of about 1,800° to 2,000° in a kiln, becomes plastic and sears over on the surface, a coating being formed there which retains the gases generated by the decomposition, under heat, of the contained compounds. This expanding gas blows the brick or the clay ball full of holes and bloats it to several times its original size.

Various clays and shales are of the proper quality and consistency for such an aggregate. The material from which the aggregate is made should be rich in compounds of metallic oxides, carbon, sulphur, sodium, potassium, or other equivalent compounds, some of which, when the material is subjected to heat, will either act as a flux in reducing the more refractory compounds or will give off gas at the desired time, or both. The use of clay or shale containing a relatively high percentage of calcium carbonate or magnesium carbonate should be avoided, as such undesirable elements, after being subjected to a temperature sufficiently high to change their form, would be detrimental to the product. The ratio of the fluxing constituents to the nonfluxing constituents can vary within wide limits, but ratios indicating fusibility at comparatively low temperatures may be commercially preferable.

Such material is widely distributed, having been found in Alabama, New Jersey, Missouri, New York, and California, and used commercially in the production of aggregates in those localities. An analysis of a typical clay or shale of which such aggregate is made is as follows:

	Per cent.		Per cent.
SiO_2	60	CO_2	2
Fe_2O_3	8	Alkalies	3
Al_2O_3	19	Water	5
CaO	1		
MgO	1		100
SO_3	1		

Such composition is found both in shales and clays. Both can be used in the manufacture of the aggregate, although the process of manufacture is slightly different. Either one weighs about 100 pounds per cubic foot in its natural state.

In general, in the production of the aggregate, the raw shale or clay must first be reduced by means of suitable crushers or disintegrators to a fineness so that all of it will pass through about $\frac{3}{16}$-inch openings. The purpose of this reduction is to obtain uniform texture and to prevent striations and laminations, which might otherwise result in the finished material. It is then burned in a kiln, according to either the wet or dry process as noted hereinafter, is taken from the kiln either in large balls or in the bloated brick, and is then crushed to the required sizes for the aggregate which, in the concrete-ship work, is not larger than passing through a $\frac{1}{2}$-inch round opening.

The aggregate burned in the stationary brick kilns is prepared as an ordinary brick for the burning. Such a product used on the Brunswick ship was made at the brick plant of the Copeland-Inglis Shale Brick Co., at Alton, near Birmingham, Ala. This material was burned in an ordinary type of down-draft dome brick kiln. The raw material, which was a shale, was prepared as for common, stiff-mud brick, and after drying to a less degree than is the practice for the production of common brick, was placed in the kiln, set rather close in columns, leaving space for swelling, and fired

rapidly. The resulting product was more or less oxidized on the surface, and lacked the uniformity possible by other methods of burning. However, most of the product was quite satisfactory. The bricks, when sufficiently cool, were taken from the kiln, crushed, and screened.

The coarse aggregate was that which passed the ½-inch screen and was retained on the $\frac{3}{16}$, the fine aggregate that passing the $\frac{1}{16}$-inch screen to dust. * * * Local coal was used for the fuel in the kilns.

While burning the aggregate at Alton, experiments were also made in burning the same material in a rotary kiln at the plant of the Coosa Portland Cement Co., at Ragland, Ala. In the experiments, the shale from Alton and the shale from the cement company's land were both used. There was practically no difference in the products of the two materials, neither was there much difference in the analysis of the shales. In this experiment the shale was prepared by passing it through Fuller mills and then directly to the kiln in the form of both a dry powder and a slurry. Bricks, also, were made at Alton and shipped to be burned in the rotary kiln with quite satisfactory results. From the experiment, though it was not extensive enough to establish the fact, it would seem that somewhat better results might be expected from the use of a slurry than from the use of a dry feed. Some very excellent material was produced during this experiment, made in an ordinary cement kiln 8 feet in diameter by 125 feet long, using powdered coal as fuel. None of this material was used in the ships.

Further experiments were made at certain other places, both with tunnel kilns and with ordinary brick kilns, but none of the material was used in practical work.

Later a contract was entered into with the Atlas Portland Cement Co. to produce light aggregates in its plant at Hannibal, Mo., using shale found on the property. The raw material here was reduced to a fineness of approximately 100 per cent through a 50-mesh screen, and introduced into a large cement rotary kiln in a dry state, with powdered coal as fuel. This burned ball coming through the rotary was passed directly into a crusher while hot and sorted at the distribution end of the kiln. Crushing the material while hot and malleable produced particles of a spheroid shape with few of the sharp corners which distinguish the cold-crushed material. In this product there is a rather large quantity of extra hard-burned small particles, which are screened out before the larger particles are crushed. These hard fines weigh considerably more than the more porous product, but on account of the expense of production they are being used in the ship work. As noted in the tables and descriptions further on, they tend to increase the weight of the concrete a few pounds over that of the concrete made from the brick aggregate. The product of the Hannibal mill is now being shipped to the Atlantic and Gulf yards.

Still later an agreement was made with the Los Angeles Pressed Brick Co. to produce the aggregate in semimuffle and downdraft kilns, using oil as fuel. In this plant the material is pugged and mixed with water and forced through brick machines and burned as ordinary brick. There is being produced here a remarkably light and satisfactorily strong material * * *

It is being used on the San Diego and San Francisco ships.

The aggregate as used in the concrete ships is as a rule being divided into two sizes, the coarse material that which passes through a screen having ½-inch round openings and is retained on the screen having $\frac{3}{16}$-inch round openings, and the fine material, that which passes through a screen having $\frac{3}{16}$-inch round openings. In the ships the concrete is mixed in the proportions of one part cement, two-third part fine aggregate, and one and one-third parts coarse aggregate, although in some of the yards these proportions have been changed to slightly different mixtures which are noticed in the various strength tests given herewith. The early specification for the concrete was that the 1:2/3:4/3 mixture with sufficient water to produce a consistency drop of 9 inches, shall develop in seven days a minimum strength of 2,500 pounds, using standard American Portland cement. In the ship the special fine-ground cement, passing 90 per cent through the 200-mesh screen, is being used. The tests, as given in the accompanying tables, indicate that the 2,500 pound would be a safe minimum for the seven-day test, with 4,000 or even 4,500 pounds per square foot for the 28-day test. The early specifications for the weight of the aggregate were that the coarse material should not weigh more than 37 pounds per cubic foot. This is somewhat lighter than the average material produced.

Tests are given in the various tables herewith.[1] Table I represents the mill test of the concrete aggregate made at Hannibal, mixed to a 1:2/3:1 proportion. These are compression tests on 6 by 12 inch cylinders and represent material shipped to Mobile, Jacksonville, and Wilmington. The screen analysis of only one of the

[1] The tables referred to contain so much detail as to make their publication in this report impracticable. The results of the tests are, however, summarized in the paragraphs that follow.

aggregates is given, but this is fairly representative of the group. From this it will be seen that the fine aggregate made at Hannibal averages about 67 pounds per cubic foot in weight and the coarse aggregate about 43 pounds per cubic foot, that the 7-day compressive strength is about 2,500 pounds per cubic foot, the 28-day compressive strength averages 4,417 pounds for 61 tests, and that the weight of the concrete for the same number of tests is 114.2 pounds per cubic foot. The low compression for 28 days is 3,246 pounds and the high 5,397 pounds, with only two testing below 3,500 and eight above 5,000 pounds. The low weight for the wet concrete is 112 pounds and the high 117½ pounds.

Table II gives the result of cylinders taken from the actual pourings of the various Atlantic and Gulf ships of concrete made with the Hannibal aggregate. From these it will be seen that the 28-day test of a 1:1:1 concrete made up of the aggregates of the sizes noted before averages well above 5,000 pounds per square inch, and that the weight is somewhat higher than the weight of the mill-tested concrete of the 1:2/3:4/3 mixture, running around 116 pounds per cubic foot. This, however, is the weight immediately after pouring, and other tests have shown that this decreases 3 or 4 pounds in the 28-day test. Table III shows the tests of various proportions and various ages of the dome-kiln aggregate used in the *Atlantus* at Brunswick, Ga.

The strengths are not quite as high as the others given, but the weights are about the same. * * * In experimental mixtures not noted here the material dropped as low as 92 pounds per cubic foot in weight, and averaged below 100 pounds. Tests on the concrete as poured in the ships show that while the weight is not quite so low it is somewhat less than with the eastern aggregates and the strength is satisfactory.

There has not been sufficient time to make long-time tests of the light-weight concrete, but a few such tests * * * show values as high as 7,200 pounds at three months, and for the standard consistency of the other tests a strength of 6,483 pounds for the same period.

Some concern is occasionally expressed as to the permeability of a concrete made with this material. A number of tests have been made, and they all show that such a concrete is as low in absorption and in permeability as concrete made with an apparently more dense aggregate. The material is not porous. While full of holes, it must be remembered that they are nonconnecting holes, so that there is no reason why water should pass through such a concrete, assuming that the aggregate itself is of a dense material. Very few strength tests on the aggregate itself have been made. Recent tests at the University of Pennsylvania laboratory show that in 1-inch cubes it has an average compressive strength of about 1,500 pounds per square inch, with values in test ranging from 1,000 to 2,500 pounds.

Commercial production of the aggregate except for the Government ships has not been started, though there are prospects that one or both of the Government contractors will continue production after the ship requirements are satisfied. There is a company in Kansas City, under the direction of Stephen J. Hayde, which is manufacturing a somewhat similar product known as haydite. This material was used in the concrete superstructure of the freight car recently exhibited in Chicago. Haydite was developed some years ago as the aggregate for sand-lime brick and is produced in a vertical kiln.

The technique of the manufacture of the aggregate is necessarily complicated, as the value of the resulting product depends so much on the quality and moisture content of the raw material, the nature of the preliminary treatment, the degree of heat, and many other details. There is no claim that perfection has been reached in the brief time in which experiments and quantity production have been under way, but the aggregate is uniform and satisfactory in quality and there is every hope that its commercial manufacture is possible. Costs to-day are not consistent, and are not therefore of much use to those contemplating the use of the aggregate for structural purposes. It seems, however, that the aggregate should be produced at the mill for $3 or $4 per cubic yard, which will weigh in the crushed state * * * in the ball or brick, uncrushed, about 60 pounds per cubic foot.

The studies, tests, and production of this aggregate have all been carried out under the direction of Rudolph J. Wig, head of the concrete-ship section of the Emergency Fleet Corporation, with C.W. Boynton and W. D. Richardson, specialists, in immediate charge of the work.

Credit should also be given to A. V. Bleininger, ceramic chemist of the Bureau of Standards, for laboratory burns of various clays to determine suitability for the purpose.

ACKNOWLEDGMENTS.

The writer again desires to thank the clay workers of the country for their cooperation, without which this report would be impossible, and also to express his thanks to the clay-working press for its support and appreciation, and to the officials who have supplied information concerning the building operations of the larger cities of the country.

PRODUCTION.

Every State is a producer of clay wares. A small production was reported from the District of Columbia and from Porto Rico. In Nevada and Rhode Island there was not a sufficient number of producers reporting to permit the publication of State totals without disclosing confidential information, so that statistics for these States have been combined with those of contiguous States.

No returns are received from the clay workers of the Philippine Islands by the United States Geological Survey, but the output of clay products in the islands in 1918 is reported by the Bureau of Insular Affairs, of the War Department, to have been valued at $455,000. This valuation, which was a slight increase over that of 1917, is not included in the production of the United States.

The value of the clay products in the United States from 1895 to 1918 is shown in figure 96 (p. 868).

137536°—M R 1918—PT 2——55

a Pottery included in "Undistributed."

b Produced by Connecticut alone and included in "Undistributed."

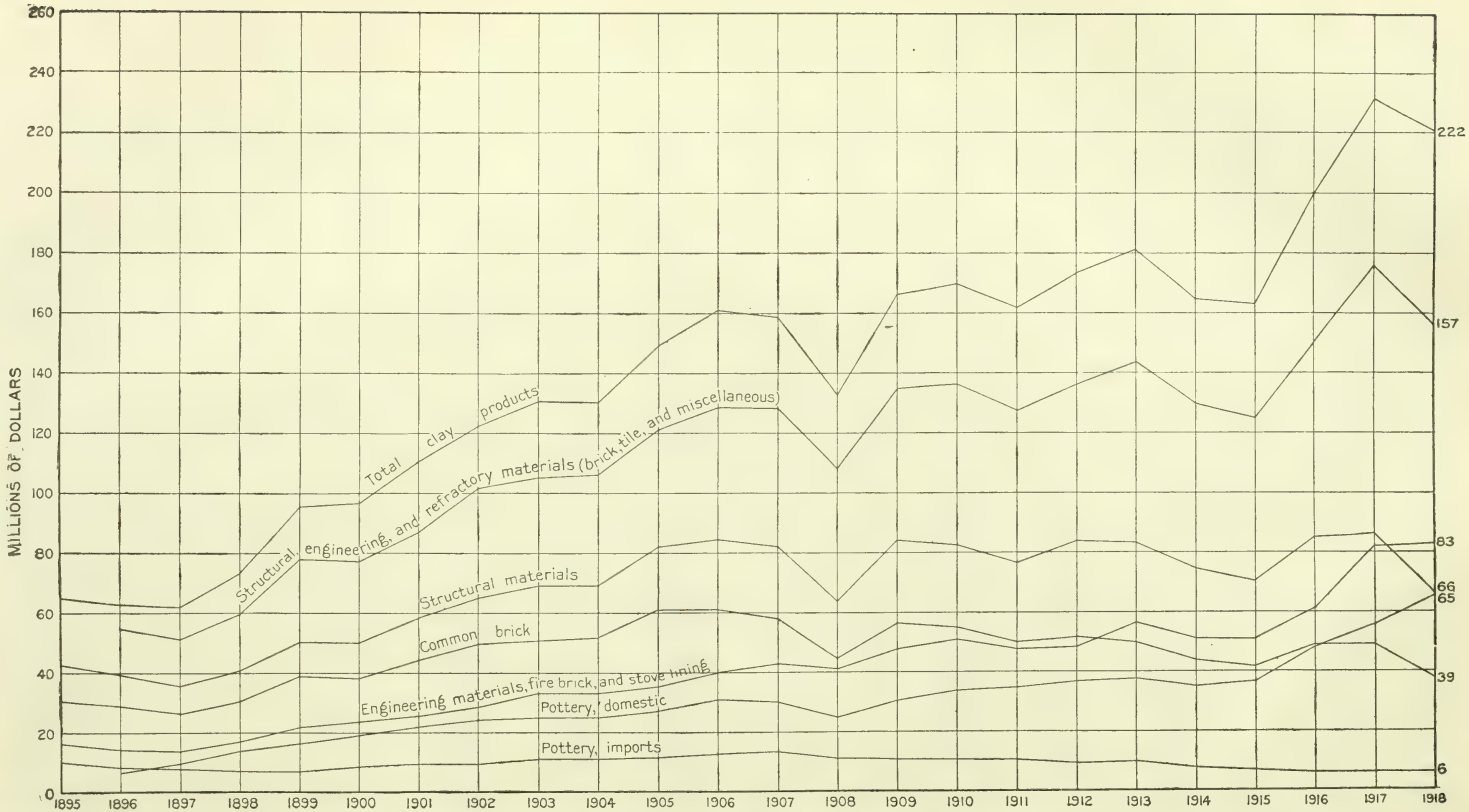

FIGURE 96.—Value of clay products sold in the United States, 1895–1918.

The value of brick and tile products as classified in this report constituted in 1918 a little less than three-fourths and that of the pottery a little more than one-fourth of the total. The total value of clay products marketed in 1918 showed a large decrease, which indicates that there was more or less stagnation in the industry. This condition, unfortunately, appears to have been true, as 34 of the 48 States reported decrease in value of output and 14 showed increase, Pennsylvania, West Virginia, Kentucky, Ohio, and Tennessee leading in increase in the order named. Pennsylvania and Kentucky owed their total increase to the increase in the value of fire brick and West Virginia and Ohio owed their increase to the value of pottery; in Tennessee the increase was due to the growth of the common brick and sewer-pipe industries and the manufacture on a large scale of acid-proof spiral rings for Government use.

Ohio has been the leading State in the value of clay products since the statistics were first compiled by the Geological Survey in 1894. The value of its output has always greatly exceeded that of the second State, Pennsylvania. In 1918 the value of Ohio's clay products was greater by $12,432,076, or 31 per cent, than that of Pennsylvania. In the first 10 States in value of output West Virginia rose from eighth to fifth place, and Kentucky from tenth to ninth; New York fell from fifth to sixth, Missouri from sixth to seventh, Indiana from seventh to eighth, and Iowa from ninth to tenth; Alabama rose from twenty-second to eighteenth place; Kansas fell from fourteenth to nineteenth, Massachusetts from nineteenth to twenty-fourth, and Minnesota from eighteenth to twenty-second; Tennessee rose from twentieth to fifteenth and Virginia from twenty-fifth to twentieth. Other changes in rank of States in value of output were insignificant. The first five States in value of output reported wares valued at $137,555,982, or 62 per cent of the total, compared with $141,848,532, or 61 per cent of the total, in 1917. The first 10 States reported wares valued at $177,040,898, or 80 per cent of the total, and the first 10 States in 1917 reported wares valued at $184,045,175, or 79 per cent of the total.

Twenty-five States that reported increase in value in 1917 decreased in 1918; 11 States increased and 9 decreased in both years; and only 3 States that decreased in 1917 increased in 1918, namely, Porto Rico, Tennessee, and Virginia.

Value of the clay products of the United States in 1917 and 1918, and increase or decrease in 1918, by products.

Product.	1917	1918	Increase or decrease in 1918.	
			Value.	Per cent.
Common brick	$47,936,344	$38,782,458	−$9,153,886	−19.1
Vitrified brick or block	10,664,560	7,145,359	− 3,519,201	−33.0

Fancy or ornamental brick	192,072	73,086	− 118,986	−61.9
Enameled brick	889,899	480,772	− 409,127	−46.0
Drain tile	11,008,163	8,196,199	− 2,811,964	−25.5
Sewer pipe	17,307,211	15,333,673	− 1,973,538	−11.4
Architectural terra cotta	6,173,550	2,658,693	− 3,514,857	−56.9
Fireproofing and hollow building tile	13,255,433	13,037,102	− 218,331	− 1.6
Tile, not drain	6,821,221	5,082,069	− 1,739,152	−25.5
Stove lining	619,882	673,953	+ 54,071	+ 8.7
Fire brick	42,501,669	51,647,639	+ 9,145,970	+21.5
Miscellaneous	8,588,879	7,455,577	− 1,133,302	−13.2
Total brick and tile	176,350,251	156,661,700	−19,688,551	−11.2
Total pottery	56,162,522	65,222,951	+ 9,060,429	+16.1
Grand total	232,512,773	221,884,651	−10,628,122	− 4.6

This table shows the general decrease in the value of clay products in 1918, as compared with 1917; 10 brick and tile and the miscellaneous products decreased, and only two brick and tile products—the refractories—and pottery increased. Of the structural materials common brick showed the largest decrease, $9,153,886, or 19 per cent, and of the engineering materials vitrified brick showed the largest decrease, $3,519,201, or 33 per cent. The largest proportionate decrease was in fancy or ornamental brick—nearly 62 per cent. This, however, is an unimportant branch of the industry, its value constituting in 1918 only 0.03 per cent of the value of clay products, or 0.05 per cent of the value of brick and tile products. Of the important structural materials architectural terra cotta showed the largest proportionate decrease—nearly 57 per cent. Fire brick, which has been rapidly advancing in importance and value in recent years, made another large increase in 1918, though not so great either actually or proportionately as in 1917.

In 1917 eight brick and tile and miscellaneous products increased and four decreased. The four to decrease in that year were common brick, vitrified brick, face brick, and architectural terra cotta. The net increase in 1917 was: Brick and tile $23,676,658, or nearly 16 per cent; pottery, $7,945,280, or 16 per cent; total increase, $31,621,938, or nearly 16 per cent.

Clay products sold in the United States, 1909–1918.

1916	13,577,006	6,466,336	9,942,912	6,475,464	7,094,149	152,673,593	48,217,242	200,890,835
1917	17,307,211	6,173,550	13,255,433	6,821,221	8,588,879	176,350,251	56,162,522	232,512,773
1918	15,333,673	2,658,693	13,037,102	5,082,069	7,455,577	156,661,700	65,222,951	221,884,651

[a] Include from 1910 to 1915 silica brick, as follows: 1910, $3,289,028; 1911, $2,520,816; 1912, $2,923,174; 1913, $3,815,806; 1914, $2,951,525; and 1915, $3,039,869.

The growth of the clay-working industries in the United States during the last 10 years is shown in this table. The total value of the products ranged from $162,236,181 in 1911 to $232,512,773 in 1917, an increase of $70,276,592, or 43 per cent. The value in 1918 was exceeded only by that of 1917 and was greater by $55,563,438, or 33 per cent, than that of 1909. Compared with 1913, the last year of normal conditions, the value in 1918 was greater by $40,595,519, or 22 per cent.

The output of common brick in the period covered ranged from 9,791,870,000 in 1909 to 3,556,519,000 in 1918, a decrease of 6,235,351,000 brick, or 64 per cent. The value of common brick ranged from $57,251,115 in 1909 to $38,782,458 in 1918, a decrease of $18,468,657, or 32 per cent. On the other hand, the average price per thousand increased from $5.85 in 1909 to $10.90 in 1918, thus nearly doubling. Compared with 1913, when the output of common brick was 8,088,790,000 brick, valued at $50,134,757, there was a decrease in 1918 of 4,532,271,000 brick, or 56 per cent, in quantity and of $11,352,299, or 23 per cent, in value. The output in 1918 was the smallest recorded by the Geological Survey and the value in 1918 was the smallest in many years. The maximum output of common brick recorded by the Geological Survey was 10,027,039,000 brick in 1906, and the maximum value of this kind of brick was $61,394,383 in 1905.

Vitrified brick or block reached its maximum output in 1909 and its maximum value in 1914. The output in 1918 was less than the maximum by 620,838,000 brick or block, or 61 per cent, and the value was less by $5,355,507, or 43 per cent. The average price per thousand in 1918 was the highest recorded; it was $2.65 higher than that of 1917 and $6.73 higher than that of 1909.

Face brick reached its maximum output and value in 1916 and, like common brick, decreased in output and value in both 1917 and 1918. The output in 1918 was less than that of the maximum by 646,368,000 brick, or 64 per cent, and the value was less by $5,369,494, or 47 per cent. The average price per thousand in 1918 was $3.38 higher than the previous high average (in 1917).

Fancy or ornamental brick, which has on the whole been declining in value, reached its minimum value in 1918 and was less by $100,987, or 58 per cent, than that of 1909.

Enameled brick, after increasing in value in 1917, showed a considerable decrease in 1918. It reached its maximum value in 1913.

Since that time, with the exception of 1917, it has steadily declined in value. Its value in 1918 was less than that of the maximum by $744,936, or 61 per cent.

Fire brick was the only brick and tile product to reach its maximum value in 1918. Fire brick has increased in value and importance almost steadily for many years, the value in 1918 being greater by $34,836,323, or 207 per cent, than that of 1913.

Draintile reached its maximum value in 1917. The value in 1918 was the smallest since 1912.

Sewer pipe reached its maximum value in 1917. Its value in 1918 was exceeded in only one year, 1917, and it was greater by $461,570, or 3 per cent, than in 1913 and by $5,011,349, or 49 per cent, than in 1909.

Architectural terra cotta reached its maximum value in 1912. Its value in 1918 was less than the maximum by $5,921,743, or 69 per cent, and was the lowest value for many years.

Hollow building tile and fireproofing reached its maximum value in 1917. Its value in 1918 was slightly less than the maximum and was greater than the value in 1909 by $8,570,394, or 192 per cent.

Tile, not drain, reached its maximum value in 1917 after an almost steady rise for nine years. Its value in 1918 was the smallest since 1908, but was larger than in any year prior to 1909.

The value of brick and tile products ranged from $125,794,844 in 1915 to $176,350,251 in 1917. The value in 1918, though much smaller than that of 1917, was exceeded in that year only and was considerably greater than that in any other year within the decade. Pottery has made wonderful progress, its value increasing almost steadily from $31,049,441 in 1909 to $65,222,951 in 1918, an increase of $34,173,510, or 110 per cent.

The value of the clay products of the United States by varieties of ware is shown in the following table. The classifications there given are not all exact, but they are as definite as it is possible to make them from the data on hand. For instance, under "fire brick" are included all material reported as such by the producers and all grades of fire brick, from those of the highest refractoriness to those which sell at a low price and can have but little value as refractory material. On the other hand, the item "cooking ware, nonrefractory," possibly does not include all the ware used for that purpose. The table is interesting in that it shows in a general way and on broad lines the value of refractory and nonrefractory wares. The details of this table, where they differ from the tables showing the value of the brick and tile and pottery products, are derived from the miscellaneous columns of those tables. Only values are given, because for many products no data of quantity are available. In fact, for some wares, notably pottery, there is no satisfactory unit of quantity. Therefore increases during the last year or two caused by the increased cost of production do not necessarily represent proportionate increases in output. In fact, as shown by other tables in this report, the quantity of some wares decreased in greater proportion than the value on account of the higher prices received.

It is not possible to draw a hard and fast line between refractory and nonrefractory wares, but the classification is based on the generally accepted use of those terms. The rapid rise in the value of refractory wares, especially fire brick, glass-house refractories, and chemical pottery, may be ascribed to the war, as those materials

are used, either directly or indirectly, in the manufacture of munitions or in the field and in the naval establishment. The most striking developments indicated in the nonrefractory wares are the great increase in the value of fire-proofing, hollow building tile or block, and porcelain electrical supplies and the decrease in value of common building brick.

An inspection of this table shows that, compared with 1913, the latest year of normal conditions, the value of clay products decreased in 1914, owing to the unsettled conditions brought about by the war. Of this decrease, however, less than one-fourth was in the refractory wares. In 1915 the nonrefractories continued to decrease, not having yet recovered from the demoralization caused by the outbreak of the war, but the refractories, owing to large contracts placed by foreign powers in this country, made a considerable increase—$3,268,290, or 17 per cent. In 1916, when the United States was in a highly prosperous condition, having recovered from the first shock of the war, nearly all branches of the industries showed great progress, refractory wares increasing in value $8,757,851, or 40 per cent, and the nonrefractory wares increasing $29,012,752, or nearly 21 per cent. In 1917 and 1918, with our Nation at war and the demand for munitions at the maximum, refractory wares increased $19,399,923, or 63 per cent, in 1917, and $9,574,254, or 19 per cent, in 1918. The nonrefractory products increased in value in 1917 only $12,222,015, or 7 per cent, and in 1918 decreased in value $20,202,376, or 11 per cent. To show further the increasing importance of the refractory products, it should be noted that the percentage of their value to the total value increased from 12.4 per cent in 1913 and 11.4 per cent in 1914, to 21.6 per cent in 1917, and to 26.9 in 1918.

Value of refractory and nonrefractory clay products of the United States, 1913–1918.

Class.	1913	1914	1915	1916	1917	1918
Refractory:						
Fire brick, including refractory block or tile, boiler and locomotive tile and tank blocks, and similar refractory products	$16,811,316	$13,476,022	$15,800,062	$24,436,873	$42,501,669	$51,647,639
Other fire brick, including some special shapes	134,635	115,144	121,747	311,052	473,713	404,657
Stove lining	535,667	520,585	459,341	601,776	619,882	673,953
Zinc retorts	(a)	576,655	823,545	1,553,691	1,514,027	1,181,334
Glass melting pots and other glasshouse refractories. (Special effort to collect statistics of these products from the consumer manufacturing for his own use was not made prior to 1915)	568,603	498,096	719,889	1,989,754	3,179,336	2,791,908
Gas retorts	65,846	41,372	23,835	35,821	(b)	(b)
Charcoal furnaces (portable)	37,217	36,243	32,865	27,280	40,568	34,552
Muffles, scorifiers, assay supplies and crucibles. (Other crucibles are included with chemical porcelain and chemical stoneware)	63,869	67,367	98,105	364,563	178,941	152,222
Saggers. (Prior to 1917 statistics for saggers were not collected from the sagger consumer manufacturing for his own use)	(b)	(b)	(b)	34,476	122,000	593,623
Chemical porcelain and chemical stoneware	c 224,894	c 246,918	c 620,401	1,054,061	1,099,432	1,769,710

a Reported by one producer only for 1913, and included with "Undistributed" refractory products. Statistics for zinc retorts were not collected prior to 1914.

b Reported by less than 3 producers. Included in "Undistributed" refractory products.

c Chemical porcelain and chemical stoneware, statistics for which were not separately collected prior to 1916, were probably partly reported under stoneware and yellow and Rockingham ware in 1913, 1914, and 1915.

Value of refractory and nonrefractory clay products of the United States, 1913–1918—Contd.

Class.	1913	1914	1915	1916	1917	1918
Refractory—Continued.						
Mantle, rings, and special ware for gas lighting and heating, including magnesia ware and refractory procelain for electric ranges and heaters	(a)	(a)	$172,261	$220,849	$247,997	$247,207
Potters' supplies. (Pins, stilts, and spurs)	$125,987	$130,740	126,780	188,643	224,343	275,545
Undistributed	148,116	132,031	22,288	.....	16,854	20,666
	[b]22,531,956	[b]18,792,698	[b]22,060,988	30,818,839	50,218,762	59,793,016
Nonrefractory:						
Common brick	50,134,757	43,769,524	42,145,292	49,357,411	47,936,344	38,782,458

Floor tile	2,483,082	881,362	912,180	1,438,231	1,325,516	1,075,474
Ceramic mosaic tile	(e)	1,520,739	1,185,787	1,308,861	1,481,505	956,456
Faience tile	731,820	675,615	635,073	814,077	1,007,005	724,734
Wall tile	1,763,992	1,584,847	1,561,865	2,000,055	2,135,323	1,595,424
Zinc condensers	(f)	176,591	260,436	512,453	496,691	408,794
Chemical or acid-proof brick block and tile, cylinders, rings, and other forms of tower packing used in the manufacture of acids at nitrate plants, and in petroleum refineries	(g)	(g)	(g)	(g)	(g)	764,588
Red earthenware	1,000,529	1,059,904	1,072,061	1,156,351	1,065,185	906,861
Stoneware and yellow and Rockingham ware	3,683,567	3,349,301	3,575,603	3,696,288	3,865,825	4,454,164
White ware, including C. C. ware, white granite, semiporcelain ware, and semivitreous porcelain ware	15,066,811	14,968,079	15,324,242	18,191,390	20,920,469	25,305,926
China, bone china, delft and belleek ware	2,424,060	2,384,686	2,330,156	3,478,372	4,805,906	6,307,349
Sanitary ware	8,214,838	7,874,269	7,993,216	11,111,417	12,636,217	11,241,138
Porcelain electrical supplies	5,737,741	4,130,270	4,671,202	7,034,420	9,451,586	12,505,970
Turpentine cups	(d)	(d)	(d)	284,218	(d)	25,289
Art pottery	400,244	374,113	446,457	619,558	870,229	722,586
Tobacco pipes	62,490	30,247	35,248	44,921	72,827	66,459
Hardware supplies and trimmings and door knobs	86,064	69,959	59,297	78,168	43,275	(d)
Toy marbles	57,000	66,325	63,948	75,304	77,243	(d)
Cooking ware, including porcelain cooking utensils (other cooking ware probably is included under stoneware)	(d)	(d)	376,532	478,805	316,991	425,822
Miscellaneous. (Mostly nonrefractory) [h]	2,769,917	2,235,665	2,072,218	2,769,536	1,804,078	1,717,557
	158,757,176	146,194,285	141,059,244	170,071,996	182,294,011	162,091,635
Grand total [b]	181,289,132	164,986,983	163,120,232	200,890,835	232,512,773	221,884,651

[a] Reported by less than 3 producers. Included in "Undistributed" refractory products.
[b] Includes silica brick as follows: 1913, $3,815,806; 1914, $2,951,525; and 1915, $3,039,869.
[c] All silo tile or block was reported under fireproofing in 1914, 1915, 1916, 1917, and 1918.
[d] Included in "Miscellaneous."
[e] Not separately classified in 1913.
[f] Reported by one producer only for 1913 and included under "Miscellaneous." Statistics for zinc condensers were not collected prior to 1914.
[g] Not separately classified prior to 1918.
[h] Including adobes, aquarium ornaments, arch brick for foundations, bitumenized block, burnt-clay ballast, chemical brick pipes, rings, and tiling for acid towers, chimney pots, pipes, crocks, tops, and thimbles, chuck (broken ware), clay pigeons, crushed tile for roofing, drop bombs, porcelain filter tubes, water filters and filter stones, flue lining, garden pottery, gas logs, grave and lot markers, Indian pottery, interlocking sewer blocks, jardinieres, Holland splits, lead corroding pots, lidded pipe, light weight aggregate for concrete ships, patent rail brick to connect street railway tracks with street paving, porcelain interiors for refrigerators, porcelain shuttle eyes and thread guides, radial chimney brick and block, radial sewer brick, ruffled brick, rustic stumps, segment block, sewer brick and block, souvenirs, stone sewer trap covers, sun dails, tunnel brick, umbrella stands, wall and chimney coping, and water tables.

BRICK AND TILE.

PRODUCTION BY STATES.

The following tables show the output and value of the building brick and other structural products of clay, and of the fire brick, paving brick, and other clay products used in engineering work, the rank of the State in these products, and the percentage of the total value of each State in 1917 and 1918. (See also fig. 97, p. 883.)

Brick and tile products in the United States in 1917.

Rank.	State.	Common brick.			Vitrified brick or block.		
		Quantity. (thousands).	Value.	Average price per thousand.	Quantity (thousands).	Value.	Average price per thousand.
20	Alabama	81,574	$557,920	$6.84	21,319	$316,914	$14.87

[a] Including adobes, assay supplies, charcoal furnaces, chemical or acid-proof brick, block and tile, cylinders, rings, and other forms of tower packing, used in the manufacture of acids at nitrate plants and in petroleum refineries, chimney pipe, and block, clay pigeons, condensers, conduits, drop bombs, flues and flue lining, gas logs, gas and zinc retorts, glasshouse pots and glasshouse supplies, grave and lot markers, light weight aggregate for concrete ships, muffles, patent rail brick to connect street railway tracks with street paving, radial brick, block and tile, scorifiers, segment block, sewer brick and block, tunnel block, wall and chimney coping, and water tables.

[b] Included in "Undistributed."

[c] Includes all products made by less than 3 producers in 1 State.

[d] The total of "Undistributed," is distributed among the States to which it belongs, in order that they may be fully represented in the totals.

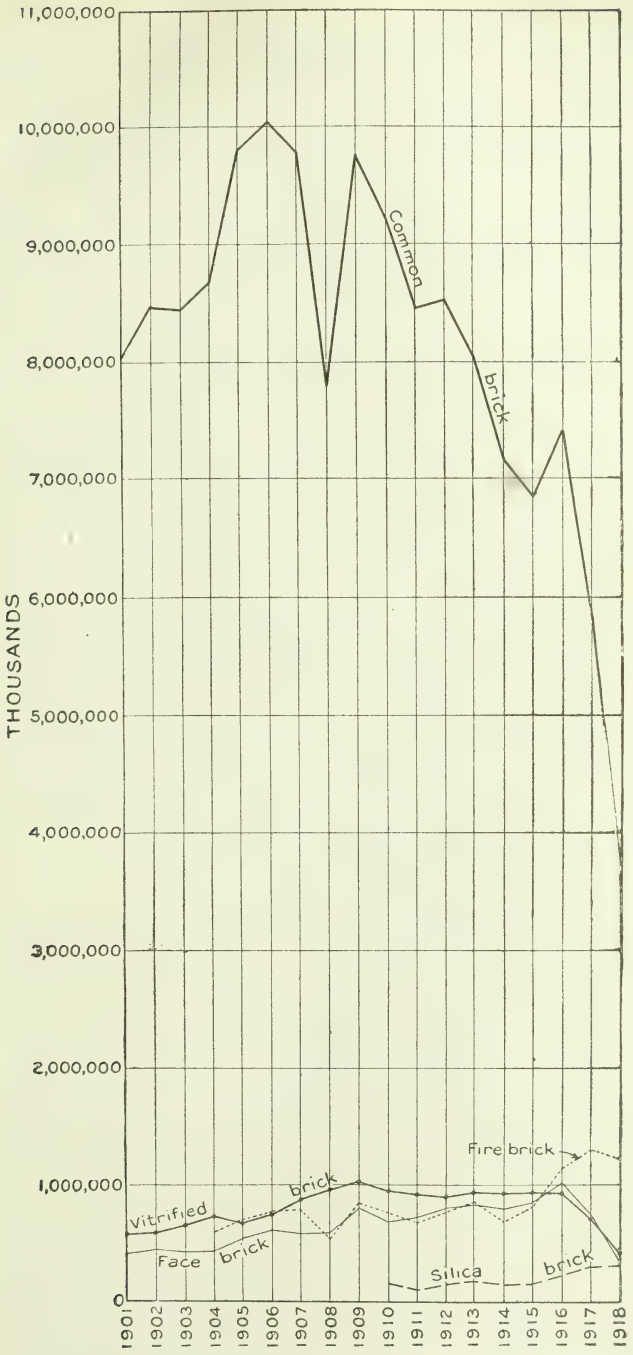

FIGURE 97.—Brick sold in the United States, 1901–1918.

Brick and tile products, as classified herein, were reported from every State, the District of Columbia, and Porto Rico. Three States, California, Illinois, and Missouri, reported every variety of ware classified as brick and tile, and three, Kansas, New Jersey, and Pennsylvania, reported all but one.

By reason of the unusual conditions prevailing in 1918 there was a decrease of $19,688,551, or 11 per cent, in the value of brick and tile products, as compared with 1917. Pennsylvania was the leading State, as for many years Ohio was second and Illinois third. There was an increase of $1,475,622, or 4 per cent, in the value of Pennsylvania's brick and tile products. Fire brick was Pennsylvania's principal clay product, its value being 65 per cent of the value of all brick and tile products in that State; common brick was Pennsylvania's second brick and tile product, constituting 14 per cent of the total; and face brick was the third, constituting 4 per cent of the total. In Ohio there was a decrease of $3,483,811, or 11 per cent. Ohio's leading brick and tile product was fire brick, constituting 26 per cent of the total, with sewer pipe second and fireproofing third. Illinois brick and tile products decreased $4,929,449, or 32 per cent. The principal product was common brick, constituting 30 per cent of the total; vitrified brick was the second product in value, 13 per cent of the total, and draintile was third. Missouri ranked fourth, and its principal clay product was fire brick, which in 1918 constituted 58 per cent of the total; sewer pipe was second in value, and common brick was third, these two products constituting, respectively, 16 and 9 per cent of the State's total value. In New Jersey, the fifth State, the leading brick and tile product was fire brick, the value of which constituted 35 per cent of the State's total; common brick was second, 20 per cent of the total; and fireproofing was third, 19 per cent of the total. Indiana was sixth in both years. Kentucky rose from ninth in 1917 to seventh in 1918; Alabama rose from twentieth to sixteenth, Virginia from twenty-fourth to twentieth, and Tennessee from twenty-fifth to thirteenth.

Brick and tile products increased in value in 11 States—Alabama, Arkansas, Georgia, Kentucky, Louisiana, Maryland, Pennsylvania, Porto Rico, Tennessee, Virginia, and Wyoming. The increase in Kentucky, Maryland, and Pennsylvania was due principally to the increase in the value of fire brick, and in Alabama, Georgia, Tennessee, and Wyoming common brick was the principal factor in the increase.

The only clay product reported from every State, the District of Columbia, and Porto Rico is common brick. This product, the value of which constituted nearly 18 per cent of the value of all clay products and nearly 25 per cent of the brick and tile products in 1918, decreased 2,308,390,000 brick, or 39 per cent in quantity, and the value decreased $9,153,886, or 19 per cent. In 1917 there was a decrease of 1,529,293,000 brick, or 21 per cent, compared with 1916. Porto Rico was the only place to show an increase in output of common brick. Ten States showed increase in value of common brick, namely, Alabama, Arkansas, Georgia, Louisiana, Maryland, Porto Rico, South Carolina, Tennessee, Virginia, and Wyoming, and every State showed an increase in average price per thousand.

Pennsylvania was the largest producer of commmon brick in 1918, rising from third place in 1917 and displacing Illinois, which was second; New York was third, Ohio fourth, and New Jersey fifth.

Pennsylvania's output of common brick in 1918 was 388,948,000, or 11 per cent of the total, a decrease of 197,684,000 brick, or 34 per cent. The value of common brick marketed in Pennsylvania in 1918 was $5,066,557, a decrease of $638,123, or 11 per cent. Philadelphia was the largest producing county in Pennsylvania. It reported 84,637,000 common brick, valued at $1,208,921, or $14.28 per thousand, a decrease of 55,631,000 brick, or 40 per cent, and of $120,886, or 9 per cent, in value, compared with 1917. The output of this county was 22 per cent of the State's total. The output in Illinois decreased 373,005,000 brick, or 50 per cent, and the value decreased $1,920,064, or 37 per cent. Cook was the leading county in the production of common brick. Its output in 1918 was 200,014,000 common brick valued at $1,508,623, or $7.54 per thousand, or 55 per cent of the State's output. This was a decrease of 297,221,000 brick, or 60 per cent, and of $1,817,607, or 55 per cent. In both of these States the brickmaking centers are the largest cities, and it is interesting to note that the proportionate decrease in output was larger in these cities than the proportionate decrease in the States at large, indicating that the falling off in building operations, where common brick finds its greatest use, was greater in the larger cities than in the smaller ones. In New York the output of common brick decreased 342,870,000 brick, or 52 per cent, and the value decreased $2,017,991, or 40 per cent. In this State the principal common brick-producing region is along the Hudson River. The production in that region was 211,574,000 brick or 67 per cent of the State's output. This was a decrease of 255,470,000 brick, or 55 per cent.

The average price per thousand for common brick, which ranged from $8.56 in Florida and Minnesota to $14.59 in Delaware, increased in every State. The largest increase was in Louisiana, $4.87 and the smallest in New Hampshire, 49 cents. In 6 States the increase was less than $1; in 11 it was between $1 and $2; in 16 it was between $2 and $3; in 8 it was between $3 and $4; and in 7 it was more than $4. The average price for the whole country increased $2.73.

Vitrified brick or block, the sixth brick and tile product in value in 1918, was reported from 26 States. This was a decrease of one, as Arkansas and Oregon, which reported none for 1917, marketed vitrified brick in 1918, and Minnesota, Montana, and Utah, which were producers in 1917, reported none for 1918. Ohio, as for many years was the leading State and reported 26 per cent of the total output and 25 per cent of the total value. This was a decrease in quantity of 81,198,000 brick or block, or 44 per cent, and of $948,411, or 34 per cent in value. The average price per thousand increased $2.40, compared with 1917. Stark County was the leading vitrified brick producing county, with Cuyahoga second and Muskingum third. Illinois ranked second reporting 21 per cent of the total output and 19 per cent of the total value in 1918. This was a decrease of 87,235,000 brick or block, or 51 per cent, and of $1,139,897, or 45 per cent, in value, compared with 1917. Livingston County was the leading vitrified brick producing county. Pennsylvania was third reporting 14 per cent of the output and 15 per cent of the value. The decrease in quantity in this State was 18,543,000 brick or block, or 24 per cent, and $143,527, or 12 per cent, in value. Alabama was fourth with 6 per cent and Kansas was fifth with 5 per cent of the output and value. These five States reported more than 70 per

cent of the entire output and value. These relative ranks have been maintained for years except that Alabama rose from eighth in 1917 to fourth in 1918, and Indiana, which was fourth in 1917, was sixth in 1918 and showed a large decrease in both output and value. Five States—Alabama, Iowa, Maine, Michigan, and Tennessee— increased in output and value of vitrified brick in 1918. Of the output marketed in 1918, 297,730,000 brick or block, or 74 per cent, was sold for paving and 105,086,000, or 26 per cent, was sold for other purposes. This was a decrease of 264,504,000 brick or block, or 47 per cent, in the output sold for paving and of 39,614,000 brick or block, or 27 per cent, in the output sold for other purposes, compared with 1917. The average price per thousand for vitrified brick or block sold for paving was $19, sold for other purposes $14.16, an increase of $2.86 and $3.19, respectively. The number of vitrified brick or block marketed in 1918 was 402,816,000, a decrease of 304,118,000, or 43 per cent. The average price per thousand ranged in the more important States from $12.75 in Texas to $27.79 in Washington.

The manufacture of face brick is the most widely distributed branch of the clay-working industries, except that of common brick, and in 1918 it was reported from 42 States, the same number of States as in 1917, but Delaware reported none for 1918 and Maine reentered the list of producers. Pennsylvania, as for many years, was the leading producer, reporting 25 per cent of the output and value in 1918. This was a decrease of 111,334,000 brick, or 56 per cent, and of $1,218,763, or 44 per cent. Armstrong was the leading face-brick producing county, and reported 23,202,000 brick, valued at $414,022, or 26 per cent of the State's total, and 27 per cent of the State's value, of this kind of brick. Ohio was second, Indiana third, Illinois fourth, and Kansas fifth in output, as in 1917. In value these ranks were the same, except that Kansas was sixth in value and Texas was fifth. All showed large decreases in output and value. The first five States reported two-thirds of the marketed product in 1918. The average price per thousand ranged from $12 in Maine, where there was a small production, to $28.73 in California.

The average price for the whole country increased $3.38. Three of the smaller producing States, namely, Idaho and Nevada (taken together), Mississippi, and South Dakota increased in output and value, and Colorado and Washington increased in value. All other States decreased in output and value. There was a decrease in the output of face brick reported in 1918 of 401,224,000 brick, or 53 per per cent, compared with 1917.

Draintile was fifth among the brick and tile products in value of output in 1918, and was reported from 37 States, an increase of 1—Maine. Iowa, Ohio, Indiana, Illinois, Michigan, and Minnesota, in the order given, continue to be the leading States in the production of draintile. These six States, together, reported draintile marketed to the value of $7,189,709, or 88 per cent of the total. This was a decrease of $2,704,094, or 27 per cent. Iowa showed a decrease of $1,748,789, or 44 per cent. The other States mentioned each showed large decreases.

Sewer pipe, the third brick and tile product in value in 1918, was reported from 25 States, a decrease of 1—West Virginia. Ohio, as for many years, was the leading State and reported 38 per cent of the entire output. The value of this output decreased $1,022,118,

or 15 per cent, compared with 1917. In 1917 it increased $1,764,445, or 34 per cent. Missouri was second, displacing Pennsylvania by a slight margin and regaining its former position. Illinois was fourth and Georgia was fifth, Georgia having risen from seventh place in 1917. The first five States reported 68 per cent of the total for 1918. All these States, except Georgia, showed considerable decrease compared with 1917. Notwithstanding the general decrease in the value of sewer pipe, 10 States, Alabama, Georgia, Kansas, Kentucky, Maine, New York, Oregon, Tennessee, Texas, and Virginia showed increase in value of sewer pipe marketed.

Architectural terra cotta was reported from 12 States, a decrease of 1—Utah. Illinois was the leading State as for many years, and reported 31 per cent of the total. The decrease in 1918 was $1,229,724, or 60 per cent, compared with 1917. New York was second, displacing New Jersey, which was third. These three States reported 62 per cent of the total for 1918. All showed large decreases from 1917. In fact, of the 12 States reporting terra cotta in 1918, only one, Georgia, showed an increase in value of output.

Hollow tile, the fourth brick and tile product in value, suffered less of a decrease than any other clay structural material. It was reported from more States than any other clay product, except common and face brick, 39 States marketing this ware in 1918, an increase of 2—Connecticut, Mississippi, and Wyoming were added to the list of hollow-tile producers in 1918, and South Carolina dropped out. Ohio was the leading State and reported 31 per cent of the output and 27 per cent of the value. The output decreased 311,906 tons, or 34 per cent, but the value of the output decreased only $18,509, or one-half of 1 per cent; the average price per ton in Ohio increased $2 or to $5.88. Iowa was second in output, displacing New Jersey, and reported 238,789 tons, a decrease of 22,699 tons, or 9 per cent. Iowa was third in value, with a slight increase—$7,192—compared with 1917. Iowa reported 12 per cent of the total output and value. New Jersey was third in output and second in value. Its output decreased 122,521 tons, or 40 per cent, and its value decreased $593,467, or 27 per cent. Illinois was fourth in output and sixth in value. Pennsylvania was fifth in both output and value, and Indiana was sixth in output and fourth in value. These six States reported 76 per cent of the output and 75 per cent of the value. Of the 36 States reporting in 1917 and 1918, 13 reported increase in output and 23 decrease; 17 States reported increase in value and 19 decrease. The average price per ton ranged from $4.05 in Mississippi to $14.21 in Louisiana. The average price for the whole country increased $1.55 per ton, or to $6.67. The output decreased 636,636 tons, or 25 per cent, compared with 1917.

Tile, not drain, includes roofing, floor, wall, ceramic mosaic, and faience tile. These products were reported from 18 States, an increase of 2—Florida and Montana. Ohio continues to be the leading State and reported 40 per cent of the output, a decrease of $620,165, or 23 per cent. New Jersey was second, and Indiana third. These three States reported 70 per cent of the total for 1918. Only three of the States that reported for 1917 and 1918, Colorado, Illinois, and Missouri, showed increase in value.

Stove lining was reported as marketed in 17 States in 1918, the same number as for 1917, but Kansas and Kentucky took the place of Iowa

and Minnesota, which reported none for 1918. Massachusetts, as for many years, was the leading State and reported 37 per cent of the total, which was an increase of $34,749, or 16 per cent, over 1917. Pennsylvania was second and New York third, as in 1917. These three States reported 68 per cent of the total.

Fire brick, now the leading clay product in value, was reported from 33 States, a decrease of 2, as Iowa, Minnesota, and Oklahoma, which were fire-brick producers in 1917, reported none for 1918, and Michigan reentered the list of producers. The quantity of 9-inch equivalent fire brick reported (1,222,352,000) decreased 81,934,000 brick, or 6 per cent, but the value ($51,647,639) increased $9,145,970, or 22 per cent, compared with 1917. The average price per thousand increased $9.66, or to $42.25. Pennsylvania continued to be the leading State, reporting 43 per cent of total output and 46 per cent of the value. This was a decrease of 22,732,000 brick, or 4 per cent, but an increase in value of $4,618,762, or 24 per cent, compared with 1917. Ohio was second, reporting 18 per cent of the total output and 14 per cent of the total value. The output in the two years was practically the same, there being an increase of 272,000 brick. The value, however, increased $1,308,133, or 23 per cent. Kentucky was third in output and fourth in value; Missouri was fourth in output and third in value; and New Jersey was fifth in output and value. These five States reported 83 per cent of the output and 85 per cent of the total value.

TILE, NOT DRAIN.

Under the head "Tile, not drain," are embraced the varieties of higher grades of tile used almost exclusively in structural work. There are numerous subdivisions and trade names for these varieties, but, owing to the small number of producers of some of them, it has been thought best to classify them as roofing, floor, ceramic mosaic, faïence, and wall tile.

The output of these wares rises and falls with building operations. Consequently every variety decreased in value in 1918 in accord with the decrease in building operations in that year.

Wall tile was the variety of greatest value in 1918—$1,595,424. If, however, floor tile and ceramic mosaics, which are used almost exclusively as floor material, are considered together, tile used for flooring was valued at $2,031,930, or 40 per cent of the total, a decrease of $775,091, or 28 per cent.

Tile, not drain, of domestic production, sold in the United States, 1915–1918.

Variety.	1915		1916		1917		1918	
	Value.	Number of firms reporting sales.	Value.	Number of firms reporting sales.	Value.	Number of firms reporting sales.	Value.	Number of firms reporting sales.
Roofing	$891,150	23	$914,240	21	$871,872	18	$729,981	16

Roofing tile, constituting 14 per cent of the total and showing a decrease in value of output of $141,891, or 16 per cent, from 1917, was reported from 10 States, California, Colorado, Florida, Iowa, Kansas, Kentucky, Missouri, Ohio, Pennsylvania, and West Virginia. These are the same States that reported for 1917, except that Florida reported roofing tile in 1918 for the first time and Illinois, which reported that material in 1917, reported none for 1918. Ohio was the leading State, reporting more than one-third of the total. California was second, and Missouri third.

Floor tile, constituting 21 per cent of the total, decreased $250,042, or 19 per cent, in value compared with 1917 and was reported from 12 States, an increase of three—Illinois, Kentucky, and Montana; the other States were California, Indiana, Massachusetts, New Jersey, New York, Ohio, Pennsylvania, Tennessee, and West Virginia. Ohio was the leading State, with sales valued at $477,679, or 44 per cent of the total, a decrease of $172,365, or 27 per cent, compared with 1917. Muskingum County was the largest producer and furnished nearly 90 per cent. New Jersey was second with wares valued at $159,862, a decrease of $121,022, or 43 per cent, and Indiana was third. These three States reported 73 per cent of the entire output of this variety of tile.

Ceramic mosaic tile was reported from nine States, an increase of three—California, New York, and West Virginia; the other States were Indiana, Kentucky, Massachusetts, New Jersey, Ohio, and Pennsylvania. There was a decrease in the value of this ware of $525,049, or 35 per cent. It constituted 19 per cent of the total in 1918. Ohio was the leading State, reporting wares valued at $361,002, or 38 per cent of the total, a decrease of $127,063, or 26 per cent, compared with 1917. New Jersey was second with an output valued at $239,828, a decrease of $134,951, or 36 per cent. These two States reported 63 per cent of the total for this variety of ware.

Faïence tile, constituting 14 per cent of the total, decreased in value $282,271, or 28 per cent. It was reported from 10 States, California, Colorado, Indiana, Kentucky, Massachusetts, Michigan, New Jersey, Ohio, Pennsylvania, and West Virginia, the same as in 1917. Ohio was the leading State and reported an output valued at $298,198, or 41 per cent of the total, a decrease of $93,130, or 24 per cent. New Jersey was second with $113,160, a decrease of $52,156, or 32 per cent.

Wall tile, the variety of greatest value, constituted 32 per cent of the total, and decreased $539,899, or 25 per cent, compared with 1917. It was reported from seven States, California, Indiana, Kentucky, Missouri, New Jersey, Ohio, and Pennsylvania. Ohio was the leading State reporting wall tile valued at $622,057, or 39 per cent of the total, a decrease of $204,853, or 25 per cent. New Jersey was second with sales valued at $360,029, a decrease of $120,952, or 25 per cent. Indiana was third. These three States reported 83 per cent of the total in 1918.

HUDSON RIVER REGION.

The Hudson River region has always held an interesting and unique place in the clay-working industries. This region, so far as the brick-making industry is concerned, is located on both sides of Hudson River and extends from New York City to Cohoes. It is

bountifully supplied with excellent clay for making common brick and is favorably located for water transportation, in many places the plants being on the water's edge. For many years this region has been the chief source of the supply of common building brick for New York City. In recent years, however, the Raritan River region in Middlesex County, N. J., has sent a considerable proportion of its output of common brick to the New York market. Hence Middlesex, together with Bergen County, N. J., has been included in the table of production of common brick along Hudson River. The year 1918 was one of great inaction. The number of producers reporting sales was the smallest since figures were published for this region, and much of the brick sold was from stock on hand, so that even fewer plants were operating than is indicated by the number of firms reporting. The lack of demand for brick in Greater New York was the principal cause of the falling off in this region. The scarcity of labor was also sharply felt, and it would have been difficult to supply anything like a normal demand for brick had it existed. The prices of common brick in New York were the highest recorded. Early in the spring wholesale prices ranged from $9.50 to $10 a thousand and they rose gradually until in December brick was sold for $15 a thousand at the dock.

Every county in this region except Middlesex County, N. J., decreased in output and value. The increase in output in this county was undoubtedly due to the large amount of structural work done by the Government and in the erection of munitions factories in New Jersey.

The output of brick in this region was the smallest recorded by the Geological Survey. The output was only about one-third as much as it was in 1912, when Middlesex County was first included, and the output of the New York-Bergen County portion of the region was less than one-fifth of that of 1909, the year of maximum production.

Common brick produced and sold in the Hudson River district, 1909–1918.

Year.	Number of firms reporting sales.	Quantity (thousands).	Value.	Average price per thousand.
1909	127	1,313,760	$6,438,642	$4.90
1910	135	1,142,284	5,544,600	4.85
1911	125	926,072	4,717,633	5.09
1912[a]	136	1,233,187	7,133,177	5.78
1913[a]	132	1,025,308	5,636,061	5.50
1914[a]	129	888,266	4,350,832	4.90
1915[a]	120	960,527	5,009,065	5.21
1916[a]	113	893,552	5,915,254	6.62
1917[a]	99	584,184	4,427,934	7.58
1918[a]	78	314,196	3,078,805	9.80

[a] Includes Raritan district, Middlesex County, N. J.

The number of brick marketed in this region in 1918 decreased 269,988,000 or 46 per cent, compared with 1917. The value of the output also decreased $1,349,129, or 30 per cent. The average price per thousand, $9.80, increased $2.22 and was the highest yet recorded. It was double the average price in 1914.

In the New York and Bergen County, N. J., portion of the region the output was 230,089,000 brick, a decrease of 275,446,000 brick,

valued at $2,151,008, a decrease of $1,568,422. The number of operators (72) in this portion of the region reporting sales in 1918 decreased 21 as compared with 1917.

Common brick marketed in the Hudson River district (from Cohoes to New York City) and in the Raritan district, N. J., in 1917 and 1918.

[a] In 1917 Rensselaer County and in 1918 Rensselaer and Westchester counties are included under Columbia.

The New York portion of the region, by reason of its greater number of operators, has always been the larger producer. For 1918 it reported 67 per cent of output and 63 per cent of the value of the entire region. The quantity of brick sold in this portion of the region in 1918 decreased 255,470,000 brick, or 55 per cent, and the value decreased $1,472,962, or 43 per cent, compared with 1917.

Of the counties included in the New York portion of the region, Ulster, as for many years, was first in output and value, its 14 operators reporting 38 per cent of the output and value in 1918. There was a decrease of 61,436,000 brick, or 43 per cent, and of $305,395, or 29 per cent, in value in this county, compared with 1917. The average price per thousand in Ulster County increased $1.75. Rockland County was second, as for many years, except in 1915, when Dutchess County was second. Rockland's output decreased 59,233,000 brick, or 66 per cent, and its value decreased $400,225, or 60 per cent. Dutchess was third in output, displacing Orange County, and fourth in value, with a decrease of 28,364,000 brick, or 50 per cent, and of $154,763, or 38 per cent, in value. Every one of the other six counties showed decrease in both output and value, compared with 1917. Every county showed an increase in average price per thousand compared with 1917. The largest increase was in Greene—$3.67; the smallest was in Orange—$1.11.

The output of the New Jersey portion of this region was slightly less than half that of the New York portion, or 102,622,000 brick.

The value of this output, $1,128,194, was slightly greater than half of that of the New York portion, owing to the higher prices received for the New Jersey brick—$10.99 a thousand. As a whole, the New Jersey portion of the region decreased in output 14,518,000 brick, or 12 per cent, but increased $123,833, or 12 per cent, in value, compared with 1917. Bergen County showed a decrease of 19,976,000 brick, or 52 per cent, and of $95,460, or 32 per cent, in value. Middlesex County was the only one in the region to show increase in output or value. The increase there was 5,458,000 brick, or 7 per cent, and $219,293, or 31 per cent, in value, compared with 1917. This increase was no doubt due to the large consumption of brick in Government work in this vicinity and in other work incident to the war.

POTTERY.

GENERAL STATEMENT.

The pottery industry of the United States in 1918 experienced another unusual year. The comparatively small imports for several years—though they increased slightly in value in 1918 over 1917—caused an increased demand for domestic ware. Even before the United States entered the war it was difficult to supply the market on account of congestion of transportation and shortage of labor, fuel, cars, and materials. As all these handicaps were greater in 1918 and were supplemented by others, the large demand by the Government for crockery for the Army and the Navy made the task of the potters still more difficult. In spite of all obstacles, however, the potters bent their efforts to the great work of helping to win the war and willingly complied with the regulations regardless of their personal sacrifices. Their burdens were not light, were frequently irksome, and were sometimes irritating, but the necessity of the Government regulations and the confusion of the hastily organized war-service bureaus were recognized as unavoidable. With the attainment of the great end, however, the sacrifices of the potters of the country were regarded as having been more than compensated, and the return of normal times should make the future of the American potter bright.

Although the value of the output was the largest yet recorded, the volume was not correspondingly large, owing to the universal increase of cost of production and the consequent high prices. In fact, the producing capacity of the potteries, which was increased but little in 1918, was reached in few if any works, the output being only from 65 to 75 per cent of their full capacity. The principal causes of the failure to reach the capacity of production were the shortage of labor due to war conditions and the indifference of some of the laborers, but scarcity of materials and fuel was a contributing factor. The high wages received, instead of acting as a stimulus, actually prevented some of the men from working full time. No extensive replacement of men by women workers, such as occurred in England and France, took place in the American potteries, though this would probably have been resorted to had the war continued much longer.

Continued efforts were made during 1918 promptly to replace men called to war, to reduce the cost of manufacture, and to increase output by introducing labor-saving machinery, such as improved stove

rooms, automatic spreading and batting-out machines, coal unloaders, and tunnel kilns, all of which made 1918 a notable year in the improvement of the equipment of the potteries of the United States. These improvements have been chiefly in the mechanical department, but efforts to improve the body, texture, decoration, and design of the ware have not been lacking.

White House dining service.—A notable event in the pottery industry in 1918 was that of placing in the White House an American-made state dining service. This service and the circumstances of its creation are described as follows:[1]

This state dining set is sure to awaken great interest throughout the country, as it is the first White House china designed by an American artist, made [chiefly] from American clays at an American pottery, burned at American kilns, and decorated by American workmen. From the largest dish to the very tiniest, every piece of this new china, which has just been delivered at the White House, is American made. And it can be added that every piece is a work of art of which any government might be proud. The china was made at Trenton, N. J. [by Lenox, Inc.]

Few realize the work involved in securing a state dining set for the White House. Months of time were consumed in the preparation of the designs for the present service. * * * The President and Mrs. Wilson desired to have the new china equal anything that could be produced in the European potteries, primarily because it was to be the first American-made state dining set and for that reason must be above criticism. They wanted it also to be exceedingly simple, and, in these war times, the decorations must have a patriotic motif.

Under these circumstances it can be imagined easily that the manufacturer and the chief artist of the firm were fully alert in filling the commission which the firm was so delighted to receive. Design after design was worked out, only to go into the wastebasket. One morning the artist came smiling into the office.

"I believe I have it," he exclaimed as he produced a paper. "Here is a design so simple and so unostentatious it can not but suit the most æsthetic taste and yet so rich in tone it commensurates with the dignity of the home of our Chief Executive. The motif is supremely patriotic—the Stars and Stripes and the seal of the United States."

The design was approved by both the President and Mrs. Wilson, who had followed the development of the designs with keen zest. They were especially delighted with the patriotic motif. There was but one change and that came from a suggestion made by the President himself. As the china was for the President's house, he thought it more appropriate that the dishes should bear the President's seal rather than the coat-of-arms of the United States, a suggestion which was accepted.

The new state dining set is a dream of beauty in chinaware, and there can be no criticism of its texture. In round numbers the service will comprise 1,700 pieces, and each piece is in two tints, a deep ivory-colored border and the cream-white china of the center of the dish. There will be no color in any of the decorations save on the service plates. The decorations are in rolled gold. Each flat piece is edged with a narrow border of the Stars and Stripes, a group of the stars alternating with a group of an exquisite conception of the President's seal.

The tea cups and the dainty after-dinner coffee cups bear golden handles and are decorated with the same design as the plates. The flaring ramekins, the double-handled bouillon cups, the breakfast-food dishes, and the little bowls to hold the relish for the oyster cocktail in the oyster plates bear the same decorations.

The large chop plates, which will be used also as cake servers, have a narrow rim of the ivory tint on which the design is painted, while the body of the plate is the cream-white fabric. The service plate is the most beautiful plate of its kind which has ever graced the White House. The border is of an indescribable deep blue, darker than the Wedgewood and yet more brilliant. It is bordered in gold in an etching of the Adam period, including an Adam

[1] First American-made china for the White House: Sunday Star, Washington, D. C., Oct. 20, 1918.

urn and scroll. The inner border bears the Stars and Stripes. The handsome seal is in the center of the plate and attracts the eye at the first glance. The plate measures 11 inches instead of the usual 10½, and thus enables the beauty of the decoration to be seen while it carries a soup or an entrée plate.

The fabric of the china—that is, the china itself—is of marvelous strength and fiber, and it is built to bear long usage. Not only so, but the great beauty of the entire service makes it a distinct addition in the field of ceramic art. The patriotic motif has been named "the President Wilson design."

Restrictions on production.—The only pottery products whose manufacture was restricted by reductions in the use of fuel by the Fuel Administration were sanitary ware and stoneware, except chemical stoneware. The allotments of fuel for sanitary ware and stoneware, except chemical stoneware, were, respectively, 50 per cent and 85 per cent, based on the average quantity of fuel used annually in the three years 1915 to 1917, inclusive. In spite of this restriction in fuel the value of ordinary stoneware made increased $588,339, or 15 per cent, though the quantity produced was probably less than that in 1917, notwithstanding an increase in the output of stoneware crocks and jars, which were used extensively in the preservation of food. The value of sanitary ware decreased $1,395,079, or 11 per cent, a decrease due to the reduction in general building operations, in which sanitary ware finds its chief use.

Potters' War Service Committee.—At the suggestion of the Chamber of Commerce of the United States representatives of the potters met at Washington in July, 1918, and organized a war service committee consisting of C. C. Ashbaugh (secretary), Ambrose G. Dale, William Scammell, Charles L. Sebring, J. E. Torbert, W. E. Wells (chairman), and H. E. Wintringer. This committee was frequently called to Washington for consultation with the various war boards. At one of these conferences the conservation division of the War Industries Board suggested that the manufacture of many articles not of first importance be discontinued during the war. In response to this suggestion the makers of different kinds of ware prepared lists of articles to be continued and submitted them for approval. The spirit of cooperation of the potters in this matter is best shown by the number of items eliminated. One company cut its list from 1,616 items to 116; another from 549 to 131; and another from 505 to 230.[1] On September 18 a conservation order was issued in the form of a schedule for manufacturers of vitrified china and semiporcelain ware which limited the articles to be manufactured during the war. It also provided that no new molds should be made for articles not on the permissible list, that no new decalcomania patterns or copperplate engravings be added, and that no new products be placed on the market even where the decalcomania patterns or copperplate engravings had already been made. Special designs already prepared by any pottery were not to be duplicated by any other pottery during the war. In the manufacture of vitrified china each manufacturer was restricted to not more than two basic hotel shapes to be known as "rolled edge and thick" or "rolled edge and quarter thick," and each manufacturer was restricted to one basic shape of dinner ware for family use. The order specified the kinds and sizes of articles to be made. For semiporcelain ware a similar schedule was included. The exemption of articles for the Govern-

[1] Crockery and Glass Jour., vol. 89, No. 2, Jan. 9, 1919, p. 15.

ment was specifically provided for. On October 30 a revised schedule was promulgated in which a few more articles were permitted, principally additional sizes of those embraced in the original order. An order was issued on October 16 by the priorities division of the War Industries Board restricting the manufacture of pottery to 50 per cent of the output of 1917. This order was subsequently modified to three glost firings a month. These orders were issued late in the year and were canceled soon after the signing of the armistice, so that they had little effect on the industry. All restrictions were removed on December 1.

Importation of clay.—The subject of the importation of clay was closely studied by the United States Shipping Board and representatives of the kaolin miners and users were called before it to show cause why the importation of English china clays should not be restricted. At this meeting the matter was fully discussed but no order of curtailment was issued. The potters agreed, however, to cooperate with the Bureau of Standards in a series of experiments with a view to working up an all-American body. Accordingly a large number of combinations of such bodies was prepared by A. V. Bleininger, of that bureau. The raw materials for these experimental bodies were assembled and combined at East Liverpool, Ohio. The clay made into these body mixtures was distributed among the East Liverpool potteries to be made into sample pieces and fired in bisque, and these samples were afterward assembled at one plant to be fired in the glost. The results of these experiments are not yet available.

PRODUCTION.

The value of all domestic pottery marketed in 1918 was $65,222,951, an increase of $9,060,429, or 16 per cent, over the value in 1917. The increase in 1917 over 1916 was $7,945,280, or 16 per cent. The value in 1918 was the greatest recorded by the pottery industry in the United States. It was $27,230,576, or nearly 72 per cent, greater than that of 1913, more than twice as great as that of any year prior to 1910, and more than six times as great as in 1897. Pottery imports also increased very slightly, and the ratio of production to consumption, 93 per cent, was the highest recorded.

Every variety of ware as classified in this report, except red earthenware and sanitary ware, increased in value as compared with 1917, and all except these two attained their maximum values. White ware, which includes the commoner grades of household wares, showed the largest increase, $4,385,457, or 21 per cent; porcelain electrical supplies, the only pottery product used directly in military and naval field operations, increased $3,054,384, or 32 per cent; and china, the pottery of highest grade, increased $1,501,443, or 31 per cent. The value of china in 1918 was four times as great as it was in 1908, a fact which, even allowing for inflated values, augurs well for the future of the pottery industry. Red earthenware decreased in value $158,324, or 15 per cent, and sanitary ware decreased in value $1,395,079, or 11 per cent. One of the causes assigned for the decrease in the red earthenware was the curtailment by the Fuel Administration of fuel to florists, who are large users of flowerpots.

The value of white ware and china, which comprise the general household wares and constitute nearly half of the value of all pottery products, was $31,613,275 in 1918, an increase of $5,886,900, or 23 per cent, over 1917. If to this sum is added the value of sanitary ware and porcelain electrical supplies, the total value in 1918 of these high-grade wares was $55,360,383, or $7,546,205 more than in 1917, and constituted 85 per cent of the value of all pottery products in 1918.

Chemical pottery—that is, chemical stoneware and chemical porcelain—which was so necessary to the manufacture of munitions of war, naturally increased greatly in both quantity and value. The increase in 1918 was $670,278, or 61 per cent. Chemical stoneware, valued at $1,547,779, increased in value $615,866, or 66 per cent. Chemical porcelain, which is a comparatively new product for the United States, was valued at $221,931, an increase of $54,412, or nearly 33 per cent.

a Under miscellaneous is included Indian pottery, valued at $12,357 manufactured on reservations and distributed by States as follows: Arizona $1,181, California $250, and New Mexico $10,926. This represents the work of several hundred Indians, but as its manufacture is largely a pastime, the number of producers is not definitely known.

b Included in "Undistributed."

c Includes all products made by less than 3 producers in 1 State.

d Of this total $221,931 represents the value of chemical porcelain manufactured in Colorado and Ohio. The remainder is chemical stoneware.

[a] Including aquarium ornaments, art pottery, chimney tubes, craequle porcelain, filter stones, gas and electric lighting and heating appliances, garden furniture, Guernsey and Oxford ware, Indian, Nilcak, Omar Khayyam, Pewabic and Rookwood pottery, pins, stilts and spurs for potters' use, porcelain door knobs and filter tubes, porcelain hardware supplies, porcelain guides for use on textile machinery, saggers, shuttle eyes and thread guides, tobacco pipes, toy marbles, turpentine cups, umbrella stands, and vases.

[b] Under miscellaneous is included Indian pottery valued at $12,357 manufactured on reservations and distributed by States as follows: Arizona $1,181, California $250, and New Mexico $10,926. This represents the work of several hundred Indians, but as its manufacture is largely a pastime, the number of producers is not definitely known.

[c] Included in "Undistributed."

[d] Includes all products made by less than 3 producers in 1 State.

The number of States producing ware classed in this report as pottery in 1918 was 38, the same number as for 1917. Two States, Maine and Montana, reported no pottery for 1918, and two States, Arizona and New Mexico, entered the list as producers of Indian pottery. There are, however, only a few States that reported the higher grades of ware. In 1918 New Jersey, Ohio, and Pennsylvania each reported every kind of ware classified in this report, and New York reported every kind except stoneware.

Ohio, the leading pottery-producing State, reported for 1918 wares valued at $25,779,654, or nearly 40 per cent of the total, an increase

of $4,425,948, or 21 per cent, over 1917. The State's principal pottery product was white ware valued at $15,779,620, which was an increase of $2,556,794, or 19 per cent, over 1917. The value of the white ware made was 61 per cent of the value of the entire pottery output of Ohio in 1918, and the State's output of this ware was 62 per cent of the output of the country. Ohio's second product in value in 1918 was porcelain electrical supplies, valued at $3,386,555, an increase of $290,393, or 9 per cent, over 1917. Columbiana County, in which East Liverpool is located, was the leading pottery-producing county in Ohio and in the country. Its output in 1918 was valued at $11,312,660, or 44 per cent of the entire output of State, an increase of $2,166,270, or 24 per cent. The value of white ware marketed in this county in 1918 was $8,951,430, or more than half that of the State's output of white ware, an increase of $1,368,576, or 18 per cent. Mahoning County was second in value of pottery, reporting ware valued at $3,591,174. Of this sum white ware constituted $3,437,674. Summit County was third with wares valued at $2,471,074. Columbiana and Mahoning counties, Ohio, and Hancock County, W. Va., contiguous territory, form the largest pottery center of the country, a center that grew out of the pottery industry started at East Liverpool, Ohio, in 1840. The value of the pottery marketed in these three counties in 1918, mostly all of the higher grades, was more than $17,000,000.

New Jersey was the second largest pottery-producing State. For 1918 it reported wares valued at $12,570,842, a small increase—$34,999—over 1917. This small gain in the value of pottery in New Jersey was due to the fact that the principal pottery product of the State is sanitary ware, which showed a considerable decrease there, as well as in most of the other States. New Jersey's output of sanitary ware was valued at $6,151,752, a decrease of $1,050,919, or 15 per cent. Sanitary ware constituted 49 per cent of the value of the State's production of pottery in 1918, and New Jersey reported 55 per cent of the entire output. Mercer County, in which Trenton is located, led in 1918 with wares valued at $10,219,282, or more than 81 per cent of the State's total, a decrease of $230,455, or 2 per cent. Sanitary ware was the chief product, valued at $5,329,846, or 52 per cent of the county's output of pottery. Middlesex County was second with products valued at $1,187,875, an increase of $199,457, or 20 per cent over 1917.

West Virginia ranks third among the pottery-producing States in value of output, and reported over 13 per cent of the total for 1918. Its pottery products (valued at $8,693,206 in 1918) increased $1,449,306, or 20 per cent, over 1917. White ware, West Virginia's principal pottery product, was valued at $5,480,581, an increase of $1,059,564, or 24 per cent. White ware constituted 63 per cent of the total value of West Virginia's pottery products in 1918. It is also a large producer of sanitary ware and reported 12 per cent of the entire output, which showed a small decrease in 1918. Hancock County, the northernmost county in the panhandle of West Virginia, just opposite East Liverpool, marketed pottery wares in 1918 valued at $4,630,302, or 53 per cent of the State's total, an increase of $941,450, or 26 per cent over 1917. Nearly all this output ($4,544,432) was white ware.

New York was fourth in value of pottery products and Pennsylvania fifth, as for many years. New York's chief pottery product was porcelain electrical supplies, of which it was the principal producer, displacing Ohio and reporting wares valued at $3,595,478, an increase of $1,577,115, or 78 per cent, over 1917. It was also the leading china-producing State, displacing New Jersey, its output in 1918 being valued at $1,964,688, an increase of $389,726, or 25 per cent, over 1917. Schenectady and Onondaga counties were the leading ones in the value of pottery, in the order named, and reported wares valued at $3,991,483, or two-thirds of the State total. These two counties reported porcelain electrical supplies as valued at $2,299,323, an increase of $1,399,322, or 155 per cent, over 1917. Onondaga county is the largest producer of china and Schenectady county is the largest producer of porcelain electrical supplies.

The first five States, Ohio, New Jersey, West Virginia, New York, and Pennsylvania, reported wares valued at $56,534,495, or nearly 87 per cent of the total. The same States reported for 1917 wares valued at $48,405,210, or 86 per cent of the total.

In considering the rank of States it should be borne in mind that the small number of producers in many of them in 1917, which makes it impossible to publish State totals without disclosing individual returns, makes the rank of all but the first few the relative and not the actual rank.

Red earthenware, which consists principally of flowerpots, was reported from 30 States, a net decrease of 1—Montana and Tennessee reported none, and Virginia entered the list of producers. Ohio, as for many years, was the leading producer, reporting more than one-third of the total and showing an increase of $44,847, or 16 per cent, over 1917. Pennsylvania was second and Massachusetts third. These three States reported nearly two-thirds of the total for 1918. The number of operators reporting this ware (102) decreased by 19 compared with 1917.

Stoneware, including yellow and Rockingham ware, was reported by 19 States, a decrease of 1—Maine. Ohio reported nearly one-half of the output and was the leading State. Its output in 1918 was greater by $298,689, or 17 per cent, than that of 1917. The number of operators reporting these wares decreased by 7.

Chemical pottery—that is, chemical porcelain and chemical stoneware—was reported from 8 States, the same number as in 1917. Indiana and Michigan reported none for 1918 and Iowa and Tennessee entered the list of producers. Chemical porcelain valued at $221,931, an increase of $54,412 over 1917, was reported from only two States in 1918—Colorado and Ohio. New Jersey was the leading State in value of chemical pottery, as in 1917, by a small margin, and Ohio was second. New Jersey's output was valued at $745,741, an increase of $273,060, or 58 per cent, and Ohio's output was valued at $714,456, an increase greater even than that of New Jersey, $285,007, or 66 per cent. These two States reported nearly 83 per cent of the total. Eighteen operators reported chemical pottery—a decrease of 1.

The pottery products of the United States having the largest total value are grouped under the head of white ware. These include the bulk of the various household wares and constituted in 1918 nearly 39 per cent of the value of all pottery products. These wares were

reported by 64 operators, the same number as for 1917, in 13 States, an increase of two in the number of States—California and New Hampshire. As there were less than three operators reporting sales in each of 8 States, totals for only 5 States are published in order to avoid disclosing confidential reports. Ohio was the leading State in 1918, as for many years, and reported wares valued at $15,779,620, or 62 per cent, of the total value, an increase of $2,556,794, or 19 per cent, over 1917. Of the 64 operators reporting for 1918, 37 were in Ohio. West Virginia was second in value of white ware and showed an increase of $1,059,564, or 24 per cent. New Jersey was third, with an increase of $198,372, or 19 per cent. These three States reported white ware valued at $22,499,270, or 89 per cent of the total for the entire country.

China was reported from the same five States as in 1917. New York was the leading State, displacing New Jersey, which was second. New York reported china valued at $1,964,688, an increase of $389,726, or 25 per cent, over 1917. New York reported 31 per cent of the total value in 1918. New Jersey showed a small decrease from 1917. These two States reported 56 per cent of the total. One more operator reported china in 1918 than in 1917, making the total 19, the largest number of operators reporting this ware.

Sanitary ware was reported from the same 11 States, as in 1917. New Jersey, as for many years, was the leading State, reporting ware valued at $6,151,752, or 55 per cent of the total. West Virginia was second and Indiana third. These relative ranks have been maintained for many years. These three States reported 76 per cent of the total output. All of them reported decreases—New Jersey, $1,050,919, or 15 per cent; West Virginia, $30,966, or 2 per cent; and Indiana, $172,793, or 13 per cent. Ohio, the fourth State in value of output, showed a small increase, $39,594, or 4 per cent.

Porcelain electrical supplies were reported by 11 States, a gain of one—California. New York was the leading State in the value of these wares, displacing Ohio, which was second. New York's output was valued at $3,595,478, an increase of $1,577,115, or 78 per cent, over 1917. Ohio, with products valued at $3,386,555, showed a gain of $290,393, or 9 per cent. New Jersey, which was third, with products valued at $2,437,133, increased $543,751, or 29 per cent, over 1917. These three States reported 75 per cent of the total value. The number of operators reporting porcelain electrical supplies in 1918 was 46, an increase of 2.

CONSUMPTION.

The value of pottery imported into the United States in 1918, added to that of the domestic pottery marketed, amounted to a total of $71,616,531. After deducting from this sum the value of the exports of domestic wares, approximately $1,479,552, and of the reexports of foreign ware, $70,099, the value of the apparent net consumption was $70,066,880, of which the domestic production was 93 per cent, the highest proportion recorded. In 1917 and 1916 it was 92 per cent. In 1915 this percentage was 86; in 1914 it was 82; and in 1913 it was 80.

IMPORTS.

The total value of imports of all clay products at the port of shipments ($6,684,200) increased $41,627, or less than 1 per cent, com-

pared with 1917. In 1917 there was an increase of $876,908, or 15 per cent, compared with 1916, and in 1916 there was a decrease of $1,034,222, or 15 per cent. The value of imports in 1918 compared with 1907, the year of greatest value, decreased $7,126,732, or nearly 52 per cent. The increase in 1918 was in pottery, the brick and tile products showing a small decrease compared with 1917. Of the imports for 1918, 96 per cent was pottery and the remainder brick and tile. The value of the imports of pottery in 1918 increased $60,266, or not quite 1 per cent; in 1917 this increase was $732,729, or 13 per cent, compared with 1916. Imports of three kinds of pottery, earthenware, crockery plain and decorated, and plain china, increased in value, and brown earthenware, tobacco pipes, decorated china, and sanitary ware decreased in value compared with 1917.

Decorated earthenware showed the largest increase, $187,336, or nearly 10 per cent. Decorated china showed the largest decrease, $140,519, or 4 per cent. In 1918 the imports of the higher grades of pottery constituted 93 per cent of the total. Brick and tile imports decreased $18,639, or 6 per cent, in 1918, compared with 1917.

The data available indicate that the volume of imports was considerably less in 1918 than in 1917.

Value of clay products imported and entered for consumption in the United States, 1909–1918.

[a] Including Rockingham ware and miscellaneous pottery products.
[b] Figures cover period from Oct. 4 to Dec. 31.
[c] Including wares classified under the act of 1913 as china and porcelain wares composed of a vitrified nonabsorbent body: Not decorated, $244,933; decorated, $2,204,851. After 1913 only wares composed of a vitrified nonabsorbent body are included.

EXPORTS.

The value of exports of domestic clay products in 1918 increased $979,311, or 14 per cent, over 1917 and reached its maximum. Of the exports 72 per cent was brick and tile, 19 per cent was pottery, and 9 per cent was unclassified. Brick and tile, valued at $5,700,371, increased $1,042,196, or 22 per cent, compared with 1917. Exports of domestic pottery, valued at $1,479,552, decreased $72,431, or 5 per cent.

Three kinds of ware and "all other" products exported in 1918 increased in value when compared with 1917, namely, fire brick,

$989,511, or 25 per cent; tile, except drain, $131,629, or 29 per cent; sanitary ware, $53,969, or 17 per cent; and "all other" wares, $9,546, or 14 per cent. Both building and fire brick decreased in number, the former 5,393,000 brick, or 45 per cent, and the latter 11,927,000 brick, or 12 per cent. Exports of building brick, earthenware, and china decreased in value in 1918, compared with 1917. The decrease in the value of building brick was $78,944, or 40 per cent, earthenware $22,207, or 3 per cent, and china $104,193, or 25 per cent. Exports of fire brick and sanitary earthenware reached their maximum value in 1918. The average price per thousand for building brick exported was $16.25 in 1917, and $17.56 in 1918; for fire brick $39.51 in 1917, and $55.81 in 1918.

Value of clay products of domestic manufacture exported from the United States, 1909–1918.

Year.	Building brick.	Fire brick.	Tile (except drain).	Earthen and stone ware.	China.	Sanitary earthenware.	All other.	Total.

Canada continues to afford the greatest market for clay products exported from the United States, wares representing 60 per cent of the value of exports going to that country, an increase of $1,062,942, or 29 per cent, compared with 1917. Canada was the best customer for American fire brick, 80 per cent of the exports going to that country; it also took 71 per cent of the building brick exported. Central America and the West Indies are the next largest consumers of American clay products, these countries taking wares valued at $1,378,244, or 17 per cent of the total in 1918, and increase of $61,306, or 5 per cent, compared with 1917. Central America and the West Indies were the best customers for tile (except drain), sanitary ware, and china. South America was third, but the exports (valued at $636,543) decreased in value $62,881, or 9 per cent. Value of exports to Europe and Mexico decreased, the former from $531,716 in 1917 to $194,555 in 1918, a decrease of $337,161, or 63 per cent. This decrease is not surprising in view of the demand on shipping for the transportation of men and munitions of war to Europe during 1918.

CLAY.

GENERAL CONDITIONS.

Clay available for the manufacture of clay products is one of the most widely distributed minerals. Hence there are clay-working plants in every State in the Union. Miners of the lower-grade clays are usually also the manufacturers, but as the higher grades of ware are reached the rule is that fewer and fewer manufacturers are also miners, until in the highest grades of ware nearly every manufacturer buys the clays he uses. The figures given in the following tables represent clay that is mined and not burned into clay products by the miner but is sold as clay. The clay thus sold is small in quantity compared with the total production and includes mainly clay used for high-grade pottery and tile, for paper making, and for refractory products.

The conditions in the clay-mining industry in 1918, as in other industries, were most unusual. As in 1917, the industry suffered from shortage and high cost of labor and from lack of transportation facilities, which curtailed production and prevented a wider use of domestic clay. Early in the year the Shipping Board in studying the means of conserving shipping for military use contemplated placing an embargo on kaolin or china clay coming from England. In March, 1918, a conference between the users of kaolin and the miners of domestic white clays was held in Washington for the purpose of ascertaining the ability of the white-clay consuming industries to substitute domestic for imported clay. After a full discussion of the subject no embargo on clay was recommended by the Shipping Board. It was shown at the conference that for certain purposes, notably in the coating of high-grade book paper and in the paint and oilcloth industries, imported clay must be used to maintain the standard of quality and economical production. The chief obstacle, it was stated, to the use of domestic clays is their lack of uniformity in quality, which was caused chiefly by lack of or improper preparation, though English clays, it is claimed by some users, have inherent qualities that are not found in the known domestic clays. It was also brought out at this conference that had it been possible to obtain

acceptable domestic clays from the southern Appalachian region, the chief domestic source of supply of white clay, the material could not have been marketed on account of lack of transportation facilities. In fact, the potters were willing to use more—but not a greater proportion—of domestic kaolin could it have been obtained.

The imports of clay, on the whole, decreased in quantity, compared with 1917, and were the smallest since 1904. The quantity imported in 1918 was 51 per cent less than that of 1914, the year of maximum imports. The value of the clay imported in 1918 was the smallest since 1915, and was $968,642, or 42 per cent, less than that of 1914. Under kaolin or china clay in the imports are included clays used in the paper, pottery, paint, and other industries. In the tables of domestic production the kaolin and paper clay are separately classified. Therefore to make a fair comparison between the imported and the domestic kaolin, the paper clay and the domestic kaolin should be added together. For 1918 they amounted to 179,694 short tons, valued at $1,459,529, as compared with 168,100 tons of imported kaolin, valued at port of shipment at $1,153,240.

FIELD EXAMINATION AND SAMPLING OF CLAY.

Another important development in the clay-mining industry was a conference in Pittsburgh, Pa., in May, 1918, between the committee on ceramic chemistry of the National Research Council and representatives of the Association of American State Geologists, various Government bureaus and war boards, for the purpose of stimulating a systematic search for ceramic raw materials of the United States. The report of the subcommittee on the field examination and sampling of clays by A. V. Bleininger and H. Ries should be of special interest to the miners and users of clays and it is quoted in part below.

In making the following recommendations regarding the field examination and sampling of clay deposits it is suggested that the geological surveys confine their attention, for the present at least, to those deposits which are located in accessible districts. Attention may also be called to the fact that certain formations are very unlikely to yield any high-grade materials. This applies to surface deposits, including floodplain, lake, estuarine, and glacial clays, ferruginous residual clays, and pre-Carboniferous formations.

The recommendations regarding field study and sampling, apply, therefore, especially to (1) plastic refractory clays, including fire clays, ball clays, and secondary kaolins, and (2) white burning residual clays.

Field examination.—The points to be considered are: (1) Location; (2) workability; (3) extent and thickness; (4) visible impurities affecting commercial value; (5) facilities for purification.

Location.—A clay deposit to be workable should be situated fairly close to lines of transportation. In general, commercial deposits should be located not farther than 6 miles from transportation lines.

Workability.—A deposit must be worked either by open pit or underground methods. In the first case the amount of overburden in proportion to the thickness of the deposit must not be excessive and should not in any case exceed 25 feet for a deposit at least 10 or 12 feet in thickness. For thinner deposits the overburden must be proportionately less. The character of the overburden must be considered with reference to its utilization for concrete, building sand, gravel, or the production of common-clay products.

For underground mining we must consider the character of the roof and floor, as well as the thickness of the bed. Without a good roof, mining becomes both costly and dangerous. To be workable by underground method the clay or shale bed should be not less than 4 feet and preferably 5 to 6 feet thick. For trackage purposes the last-named figure is essential. Where it is possible to mine coal in conjunction with the clay, a thinner seam may be workable. Some deposits are workable by circular or square shafts, lined with cribwork. The question of drainage, whether natural or artificial, should also be considered.

Extent and thickness.—These points should be carefully determined for the purpose of estimating the tonnage. Careful measurements should be made of the thickness of the deposit, wherever outcrops can be found as well as where records are available. The geologic nature of the formation should also be taken into consideration, to serve as a guide for judging the persistence of the beds. By the use of levels and sections in neighboring ravines and on road cuts a continuous section can often be obtained. Where outcrops are insufficient to yield satisfactory information, borings should be made with a 2-inch auger or core. A post-hole auger may sometimes be used advantageously in digging through the overburden.

Occasionally the cooperation of the owners of the land on which the promising clay has been found can be secured in extending the sampling to boring and sinking test pits. This method gives more accurate data. This work should, however, always be done under the jurisdiction of a survey official.

Visible impurities affecting commercial value.—The impurities most easily discovered are sand, concretions of limonite, siderite, pyrite, or calcite, gypsum crystals and rosettes. Calcium carbonate may be present in a fine state of division, in which case its presence can be detected by acid. Residual clays from limestone may contain chert. These lumpy impurities can not be easily eliminated, unless the clay is washed, or unless they occur in definite bands.

Sand grains, consisting of quartz, feldspar, or mica, can be removed by washing, even if uniformly distributed through the clay, provided the clay disintegrates readily, and yields a sufficient percentage of washed product. If the clay is to be washed, to be of commercial value it should yield at least 15 per cent of refined product, provided it is of white burning character.

Facilities for purification.—In order to make washing practicable a sufficient supply of clean water should be available. There should also be a sufficient level area for location of the washing plant site, suitable space for disposal of tailings, and convenient drainage of waste water.

Sampling of deposit.—Samples are usually taken from the outcrop. This may either be an inclined or a horizontal surface. Preparatory to taking the sample, the surface must be carefully cleansed of all dirt and stained clay. Trenching 18 inches wide and 12 inches deep should, if possible, be dug across the outcrop at right angles to the strike. The spacing of the trenches is to be determined by the extent of the outcrop and uniformity of the clay. For an exposure several hundred feet in length, trenches can be dug 100 feet apart. The size of the sample is to be determined by the extent of the outcrop.

As the method outlined above will yield more material than is necessary for even a complete series of tests, the clay from the different trenches can be reduced to lumps not exceeding 2 inches in diameter, mixed together, and then reduced by quartering to about 50 pounds, which is to be sent to the testing laboratory, a lump sample of about 10 pounds being sent to the office of the Survey. The quartering should be done on a heavy sail cloth at least 6 feet square and as the amount of material is reduced, the lumps should be further broken up.

If the deposit shows distinct differences as regards structure, color, and texture, each bed showing these individual differences should be sampled separately, provided these beds are sufficiently thick to be mined by themselves, or can be thrown out if undesirable.

If the deposit is being worked and a clean face is exposed, the sampling cut can be made narrower and shallower than specified above, a sufficient number of cuts being taken to give a quantity of at least 200 pounds. Where the clay is stored in stock piles the sample may be taken from these, provided they are representative. At least one-half of the sample should be taken from the lower third of the pile. In the case of clays that are being purified, a sample of both the crude material and the clay as prepared for the market should be taken.

The samples collected as outlined above shall be placed in clean, tight-weave, strong sacks. The sample should be numbered, the number being stamped on one end of a tin or zinc tag, 3 by 1 inch. This tag is to bear the sample number and name of the Survey sending it. The tag is to be bent in half and attached to 2 feet of cord, the end of which is tied in the neck of the sack. The sack should be shipped with a linen label, bearing address and sample number and name of sender.

CLAY CONFERENCE.

Another noteworthy event of this year was the meeting in Pittsburgh, Pa., on October 15, of many miners of high-grade clays and of representatives of the War Industries Board and of the United States

Geological Survey for the purpose of forming a war service committee. This committee was called at the suggestion of the Chamber of Commerce of the United States. The function of this committee was to afford the industry a channel through which it could keep in touch with the War Industries Board and other Government boards and departments. At this meeting a war service committee was elected, subject to the ratification by the industry, as follows: D. R. Edgar, Robert S. Finney, C. J. Hand, R. D. Hatton, F. S. Bell. J. M. Manor, Henry M. Minor, and P. J. Ryan. The armistice came so soon after this meeting that the committee was unable to accomplish anything or even to complete its organization.

HIGH-ALUMINUM CLAYS.

Inquiries for a supply of clay containing 35 per cent or more of alumina continue to come to the Geological Survey. Many such clays are known in Arkansas, California, Colorado, Georgia, Indiana, Kentucky, Mississippi, Missouri, New Jersey, Ohio, and Pennsylvania, and no doubt search in other States will find many more. The most interesting development along this line is that of the diaspore clay of the flint-clay deposits of eastern central Missouri. The preliminary report[1] on this subject is as follows:

DIASPORE CLAY IN MISSOURI.

The presence of flint clay deposits in eastern central Missouri has been known for a good many years. The principal district in which they occur includes the counties bordering Missouri River in the north and south from St. Louis County as far west as Callaway and Osage. To the south Maries, Phelps, and Crawford counties are also included.

Pockets of flint clay in large number extend from Truesdale, Warren County, past Montgomery City to Fulton, Callaway County, on the north. On the south they are even more abundant from Jeffriesburg, Franklin County, west to Belle, Maries County, and from Leasburg, Crawford County, west to Rolla, Phelps County.

The opening of the first flint clay pits dates back nearly 50 years ago, almost with the beginning of railroad transportation in the district. Since this time there has been continuous but shifting and fluctuating activity and over 100 flint clay pits have been opened. Developments have formerly and still are confined to narrow zones bordering the railroads—zones whose outer limits are determined by the balance between cost of haulage and price obtained for the clay. At present no clay is hauled farther than five miles. The productive belts border the Wabash, the St. Louis-San Francisco, and the Chicago, Rock Island & Pacific railroads. The first two roads have long been transporters of flint clays, but the Chicago, Rock Island & Pacific did not enter the field until 1902, following its extension westward from Franklin County.

The flint fire clay has always been the principal type of clay produced in this district. This varies from a comparatively soft creamy white, nonplastic clay of an oily nature, to harsh hard dull gray varieties, not unlike the mineral from which it receives its name. A light-colored plastic clay (bond clay) is quite commonly associated with the flint clay. In some pits it is a decomposition product at the top of the deposits; in others it forms the major part of the deposit.

The most recently discovered and important associate of the flint clay is diaspore clay, an aluminum-rich variety formerly discarded because of its sandy rough texture, and of the blistering and distortion it caused when fired. This type of clay has been found chiefly along the Chicago, Rock Island & Pacific Railway from Gerald west to Belle, with one or two smaller lenses in pits near Hofflins, on the St. Louis-San Francisco line. The presence of this rough type of clay has until recently been regarded as detrimental or worthless and to-day abandoned pits may be found where large bodies of it were left. The peculiar texture of the diaspore clay and its common association with the flint clay, frequently as a core near the center of the deposit or as rounded boulders in the overlying weathered clay, aroused interest of Dr. W. S. Cox,

[1] Missouri Bur. Geology and Mines Bienn. Rept. State Geologist, Fiftieth General Assembly, 1919, pp. 17–20.

of Cuba, Mo., who had for several years been a producer of flint clay. Samples were sent by him to numerous firms for testing and valuation, and chemical analyses were obtained.

In texture diaspore clay ranges from a compact hard blue or gray flint clay with scattered flecks of white or bluish white and an occasional minute oolite through a true oolitic form to a rough, porous ash-colored mass not unlike the light-colored varieties of bauxite. Red varieties of the clay are also found. It had been discovered that where this type of clay was found there was an enrichment of alumina, depletion of silica, and frequently a very low lime and magnesia content. An analysis made on a sample of the clay by Mr. W. E. Oyler, Missouri Geological Survey, Rolla, Mo., showed the following results:

Analysis of diaspore clay from Missouri.

	Per cent.
Moisture	0.60
Loss on ignition	14.00
Silica (SiO_2)	9.30
Alumina (Al_2O_3)	73.73
Iron oxide (Fe_2O_3)	.57
Soda (Na_2O)	2.00
Potash (K_2O)	.52
	100.72

The diaspore clay is therefore quite distinct from the flint clay in both texture and composition. It is apparently made up from particles and oolites of the mineral diaspore (AlO, OH) containing 85 per cent aluminum and 15 per cent water, interbedded in more or less flint clay. This composition gives rise to the name "diaspore clay," tentatively used here.

Edgar T. Wherry, of the Bureau of Chemistry, Washington, D. C., recognized the mineral in a sample sent from Rosebud as diaspore or diasporite [1] and later wrote:[2] "The recognition of diasporite, in comparatively large masses in association with clay suggests that this mineral may possibly prove to be of commercial value, either as an ore of aluminum or for the manufacture of abrasives."

Dr. Cox has succeeded in introducing the disapore clay into a broad field of usefulness, and it promises soon to assume an important place among aluminum ores; blended with clay, it supplies the desired aluminum content in certain types of refractories; refined and bonded, it is used as an abrasive under special trade names. Shipments in commercial quantities were begun about the first of this year (1918).

The deposits are large, often forming the cores of the flint clay pockets of the Rock Island district, and in a few of those along the Frisco [lines]. As developments are extended farther out new deposits are likely to be discovered and an ample supply is assured.

Diaspore clay is generally shipped under two trade names—"Ashy clay," the rougher, porous variety richest in aluminum, the "Massillon clay," a leaner variety with fewer and smaller oolites and of a more compact texture.

An investigation of this new clay and its associations is now being carried on by the Bureau.

PRODUCTION.

The clay sold as such in 1918 amounted to 2,976,361 short tons, a decrease of 137,483 tons, or 4 per cent. This clay was valued at $8,332,641, or $2.80 a ton, an increase of $290,095, or 4 per cent, and of 22 cents in the average price. Kaolin, stoneware clay, and miscellaneous clay showed increase in output and value. No kind of clay reached its maximum output in 1918, although kaolin, paper clay, ball clay, fire clay, and miscellaneous clay, reached their maximum value in that year. The maximum value of clay marketed was attained in 1918, and the maximum quantity was reached in 1917. The increase in output of kaolin in 1918 was 6,084 tons, or 19 per cent, and the value of this material increased $89,731, or 30 per cent, compared with 1917. Stoneware clay increased in output 5,448, or

[1] Am. Mineralogist, vol. 2, pp. 144, 1917. [2] Idem, vol. 3, pp. 154, 1918.

7 per cent, and in value it increased $33,259, or 29 per cent. Only one kind of clay—slip—decreased in output and value. Paper clay showed the largest increase in value, $105,999, or 11 per cent, except miscellaneous clays, which embrace a variety of clays. Paper clay showed a large decrease in output, 32,724 tons, or 19 per cent. This decrease was principally in Georgia. Ball clay decreased in output 17,510 tons, or 16 per cent, but increased in value $21,391, or 4 per cent. The largest decrease in output—42,939 tons, or 18 per cent, was shown by fire clay, but it increased in value $38,969, or less than 1 per cent. Fire clay ranked first in production and constituted 77 per cent of the output and 68 per cent of the value of the domestic clay marketed in 1918. Paper clay ranked second, with 5 per cent of the output and 13 per cent of the value; ball clay was third, with 3 per cent of the output and 7 per cent of the value. The average price per ton increased for every kind except slip clay. The greatest increase in price was in paper clay, $2.02, or to $7.54; ball clay increased $1.27, or to $6.57; kaolin 85 cents, or to $10.30; stoneware clay 29 cents, or to $1.69; fire clay 6 cents, or to $2.46. Slip clay decreased 47 cents a ton, from $4.15 to $3.68.

a Including bentonite, brick clay, leverrierite, modeling clay, sewer-pipe clay, terra-cotta clay, and bog clay used in lead-pencil manufacture.
b Included in "Undistributed."
c Includes all clay reported by less than 3 producers in 1 State.

Forty-one States, as in 1917, reported sales of clay in 1918, and the leading seven States, as in 1917, in the order of quantity of clay marketed, were Pennsylvania, Missouri, Ohio, New Jersey, Illinois, California, and Georgia, except that in 1917 Georgia was sixth and California was seventh. These seven States reported 2,210,126 tons of clay, in 1918, or 74 per cent of the total; their output in 1917 was 2,306,770 tons, also 74 per cent of the total; and the decrease in 1918 was 96,644 tons, or 4 per cent, compared with 1917. In value of output the leading seven States were Pennsylvania, Missouri, New Jersey, Ohio, Georgia, Illinois, and Tennessee. The value of the clay marketed in these States in 1918 was $6,108,528, or 73 per cent of the total; in 1917 the value was $6,025,682, or 75 per cent of the total. In all these States, except Georgia and Tennessee, fire clay was the principal product in 1918. In Pennsylvania fire clay constituted 89 per cent of the output and 83 per cent of the value of the clay marketed; in Missouri it was 97 per cent of the output and 92 per cent of the value; in Ohio, 86 per cent of the output and 92 per cent of the value; in New Jersey, 84 per cent of the output and 86 per cent of the value; and in Illinois, 79 per cent of the output and 90 per cent of the value. In Georgia the principal clay marketed was the well-known white "plastic kaolin" or paper clay of the central part of the State, 54 per cent of the output and 86 per cent of the value of the State total being of that variety.

Fire clay.—Fire clay was reported from 32 States. In 1918, Pennsylvania was the leading State, displacing Missouri, the leading State in 1917. Pennsylvania's output in 1918 was 529,487 tons, or 23 per cent of the total, and was valued at $1,403,545, or 25 per cent of the total. This was an increase of 88,143 tons, or 20 per cent, and of $285,202, or 26 per cent, compared with 1917. Missouri's output of fire clay in 1918 was 452,792 tons, or 20 per cent of the total, a decrease of 38,882 tons, or 8 per cent; the value was $1,101,652, or 19 per cent of the total value, and a decrease of $205,069, or 16 per cent. Of the production of fire clay in Missouri in 1918 St. Louis City and St. Louis County reported 338,564 tons, valued at $902,001, or 75 per cent of the State's output and 82 per cent of its value, a decrease of 67,684 tons, or 17 per cent, and of $271,661, or 23 per cent, compared with 1917. Ohio was third in output and fourth in value. Its output was 15 per cent of the total and was 347,686 tons, a decrease of 1,840 tons, or less than 1 per cent, and its value was $683,533, an increase of $153,693, or 29 per cent. New Jersey, as in 1917, was fourth in output and third in value of fire clay, the State reporting 240,268 tons, or 10 per cent of the total, valued at $918,390, a decrease in quantity of 40,830 tons, or 15 per cent, but an increase of $102,883, or 13 per cent, in value. Middlesex County is the great fire-clay producing center of the State, and 207,459 tons, or 86 per cent of the State's total, was reported from that county. Illinois was fifth in output and value, reporting 6 per cent of the total output and 7 per cent of the total value. In Illinois the output, which was 133,585 tons, decreased 17,070 tons, or 11 per cent, and the value decreased $364,273, or 49 per cent, compared with 1917. The average price per ton of fire clay in 1918 in these States was: Illinois, $2.79; Missouri, $2.43; New Jersey, $3.82; Ohio, $1.97; and Pennsylvania, $2.65; in 1917 the corresponding prices were: Illinois, $4.89; Mis-

souri, $2.66; New Jersey, $2.90; Ohio, $1.52; and Pennsylvania, $2.53. It thus appears that in only one of these States, Illinois, was there a large decrease in average price. This was caused by the decreased demand for clays from Illinois suitable for crucibles and other high-grade products for which a very high price had been obtained.

Kaolin.—Kaolin, the purest form of clay and in some respects the most valuable, was reported from 10 States, the same number as for 1917. Colorado, which reported kaolin in 1917, reported none for 1918, and Mississippi appeared as a producer. On account of the small number of producers in seven of these States it is impossible to publish figures of production without disclosing confidential information. The principal source of domestic kaolin is the Southern States, which reported seven-eighths of the output. North Carolina was the largest producer and reported nearly one-half of the output and value.

Paper clay.—Paper clay, the second clay in output, value, and average price per ton, whose principal use is indicated by its name, was reported from three States, a decrease of one—Illinois. Georgia was the leading producer and reported 54 per cent of the output and 52 per cent of the value, a decrease of 33,149 tons, or 30 per cent, and of $21,624, or 4 per cent. The average price per ton in Georgia increased $2.01 to $7.26. South Carolina was also a large producer of paper clay, these two States reporting 81 per cent of the output in 1918. The decrease in output in 1918 was due largely to the lack of transportation facilities to move the material to the markets in the Northern States.

Ball clay.—A plastic white-burning clay that finds its principal use in white-ware bodies, was reported from six States in 1918, the same number as in 1917, but Alabama dropped out and Maryland entered the list of producers. The Southern States produced nearly the entire output in 1918, 93 per cent of the output coming from that region. Tennessee was the leading State. It reported 37 per cent of the output and 33 per cent of the value, a decrease of 7,257 tons, or 18 per cent, but an increase in value of $27,314, or 16 per cent. The average price per ton increased in this State $1.73 to $5.87.

PRODUCTION BY USES.

In response to a considerable demand for information in regard to the uses to which domestic clays are put an effort was made to obtain such data for 1918. As with all new statistical investigations where the data are derived from voluntary reports by correspondence, the result of the first canvass is not entirely satisfactory, though it is believed that the data given in the following table are sufficiently accurate to serve as a guide in a study of the uses of domestic clays. The principal obstacle to obtaining satisfactory data is that many producers do not know the uses to which the clays they ship are put. This is especially true of clay that is sold through brokers, such as much high-grade clay. Some of the miners may know in a general way the purposes for which their clay is adapted but could not give definite figures of the quantity sold for each use, and many of them do not appear to know even the uses to which their clay is adapted.

With the beginning of the publication of these data it is hoped that the miners of clay will endeavor to learn more concerning the utility

of their product, as the advantage accruing from such knowledge is manifest, many clays no doubt being better suited to other uses than those to which they are put.

In considering these figures it should be borne in mind that they represent only the clay sold as clay by the original producers and do not include the much greater quantities of clay that are burned into clay products by the miners. Thus, the large quantities of clay used in the manufacture of building and paving brick, draintile, sewer pipe, fireproofing, etc., are not included. Therefore these figures are interesting chiefly in showing the clay marketed for the higher grades of wares. Apparently the largest use of clay is the use by foundries and steel works for lining converters, cupolas, ladles, etc. This use is proportionately large because probably none of the users mine the clay themselves; hence all such clay is purchased and has been reported by miners. On the other hand many if not most of the makers of fire brick mine at least a part of their clay. Therefore the clay reported for fire brick represents only a small proportion of that actually used in making this ware. Kaolin, paper clay, ball clay, slip clay, and stoneware clay being produced almost exclusively by nonmanufacturers, the figures for these clays represent practically their entire output.

A study of the table shows that 834,789 tons, or 28 per cent of the total, was used in foundries and steel works, for converter and cupola linings, etc.; 621,788 tons, or 21 per cent, in fire brick or block; 149,983 tons, or 5 per cent, in zinc retorts and condensers; and 92,114 tons, or 3 per cent, in saggers. A total of 125,321 tons, or 4 per cent, of domestic clay of all kinds was reported as having been used in high-grade pottery and tile. Of this total the white ware or general ware industry consumed 69,119 tons, porcelain electrical supplies 24,232 tons, sanitary ware 16,799 tons, and tile 11,935 tons. Stoneware and chemical stoneware consumed 80,051 tons, or nearly 3 per cent of the marketed domestic clay. The principal refractory uses, foundries, steel works, converter and cupola linings, fire brick, zinc retorts, and condensers and saggers, consumed 1,698,674 tons, or 57 per cent of the domestic clay marketed in 1918. The paper-making industry consumed 98,163 tons, or 3 per cent of the total. Other interesting uses of domestic clay, though not so large as the foregoing, are in the oilcloth, paint, and enameling industries, 2,858 tons of clay having been reported sold for making oilcloth, 8,099 tons for paint, and 599 tons for enameling. Crayons for tailors used 352 tons of domestic clay; 59,290 tons of clay was reported as having been sold for glasshouse pots, blocks, tiles, supplies, etc., and 8,475 tons for graphite crucibles, pencil leads, etc. These figures are the more interesting when it is considered that clays for many of these uses were largely imported before the war. Other unique uses of clay are in the manufacture of artificial abrasives, phonograph records, and picture molding, and in water purification, 13,197 tons having been sold for artificial abrasives, 1,629 tons for phonograph records, 25 tons for picture molding, and 250 tons for water purification. Of the clay marketed as such 18 per cent was unclassified by the miner according to uses.

Of the domestic kaolin marketed in 1918, 21,190 tons, or 56 per cent, was sold for high-grade pottery; 6,383 tons, or 17 per cent, for

paper; and 7,500 tons, or 20 per cent, for fire brick or block. Kaolin was one of the best classified by the shippers, practically all—99.6 per cent—of the output being reported by uses.

The principal use of paper clay marketed in 1918, as indicated by its name, was in the making of paper, 89,422 tons, or 63 per cent of the total, having been shipped for that purpose. The pottery and tile industries used 25,842 tons, or 18 per cent, of the total clay of this kind. The cement industry took 7,877 tons, or 6 per cent, presumably for the manufacture of white cement. The paint industry consumed 6,654 tons, or 5 per cent. The other uses of paper clay are comparatively small, the oilcloth industry taking 2,858 tons and the phonograph industry 1,600 tons. No use was specified for 4 per cent of the paper clay marketed in 1918.

The principal use of domestic ball clay in 1918 was in the high-grade pottery and tile industries, 67,362 tons, or 75 per cent, having been sold for these uses. The next largest specified use was in saggers, for which 4 per cent of the output was reported. This clay was also reported as having been marketed for use in making glass pots, etc., fire brick, pins, stilts, and spurs for potters' uses, etc.; the use was not reported for 8,216 tons, or 9 per cent of the output.

Slip clay, an easily fusible material, found its chief use in the manufacture of artificial abrasives, 6,593 tons, or 49 per cent, going to that use, and 4,228 tons, or 31 per cent, being used for glazing. Slip clay showed the smallest proportion of unspecified shipments—0.3 per cent.

Fire clay, as its name would indicate, finds its greatest use in refractories, 96 per cent of the classified output being marketed for uses where refractoriness is the prime requisite. The term "fire clay" is elastic, and no doubt there are reported under this head clays of very little refractory value as well as fire clays of the highest grade. Hence the uses of this clay may be varied. Apparently the largest use of fire clay is in the foundries and steel works for converter and cupola linings, 809,562 tons, 35 per cent of the classified fire clay, having been marketed for those purposes. As stated elsewhere, however, this proportion is more apparent than real, for the clay used in these industries is probably all purchased, whereas much if not most of the clay used in fire brick is mined by the manufacturers, and hence would not be included in the figures here given. The clay sold for fire brick amounted to 604,704 tons, or 26 per cent, and that for zinc retorts and condensers to 149,983 tons, or 7 per cent of the total. Next to refractories and high-grade pottery and tile the largest use of fire clay was in the manufacture of terra cotta, which took 12,854 tons. Other uses to which "fire clay" has been put are in the manufacture of enamel ware, paper, paint, asbestos products, cement, artificial abrasives, crayons, and chemicals. Fire clay showed the largest proportion of unspecified clay, 20 per cent.

Stoneware clay, which is a refractory or semirefractory clay, is used chiefly, as its name would indicate, in the manufacture of stoneware and chemical stoneware, 79,481 tons, or 92 per cent, of the output going to those uses.

Domestic clay sold in the United States in 1918, by uses, in short tons.

The imports of clay, though not large, are nevertheless essential under present conditions to some industries. This is especially true of the white ware, porcelain, sanitary ware, paper, paint, and oilcloth industries, which use large quantities of imported kaolin or china clay. Prior to 1914 comparatively large and increasing quantities of high-grade plastic fire clay were imported from Germany for use in the manufacture of crucibles, glasspots, abrasives, pencil leads, and enameled ware. Some of the English clays have also been used for these purposes, but by far the larger part of the clay for these uses came from Germany. In the absence of these clays domestic substitutes have been sought and found more or less successfully. The consensus of opinion of the users seems to be, however, that the domestic clay as marketed is not so satisfactory as the imported. Many hold that with proper preparation and blending satisfactory clays will be developed in the United States. In addition to the kaolin and fire clay imported from England, much, if not all, of the so-called "unwrought" clay was English ball clay used principally in high-grade pottery. Imports of all of these clays have decreased during the last few years, those from Germany, of course, ceasing entirely. The prices per ton also seem low. But these prices are at the port of shipment and when the cost of freight and other expenses are added the price delivered at the point of consumption is often more than double.

In view of the prevailing conditions in 1918 a decrease in imports of clay, which come almost entirely from Europe, was to be expected. To add to the difficulties the British shipping authorities in the summer of 1918 ruled that no exports of clay would be permitted from England to Boston, New York, or Philadelphia. The object of this order was to prevent congestion in these ports and to make the ships available for more important cargoes. As nearly all clay imports in 1918 came from England, and as these ports were the principal ones to which clay is normally shipped, the effect of the order must have tended to reduce imports. As a matter of fact, clay imported and entered for consumption did decrease 72,701 tons, or

27 per cent, compared with 1917. The value of the imported clay also decreased, but not in so great proportion. This decrease was $123,265, or 9 per cent. For many years the chief clay imported has been kaolin or china clay. In 1918 it constituted 86 per cent of the quantity and 87 per cent of the value of the imported clay. The imports of kaolin decreased 72,929 tons, or 30 per cent, and were only about one-half as great as they were in 1914, the year of maximum imports. The value of imported kaolin decreased $162,529, or 12 per cent. Compared with 1914, the decrease in value was $774,185, or 40 per cent. The average price per ton of kaolin at the port of shipment in 1918 was $6.86, an increase of $1.40. When, however, freight, insurance, duty, etc., are added the price to the consumer is very much greater than the figures given. In fact, quotations given in New York trade journals for imported china clay ranged from $17.50 to $40 per ton in 1918, compared with $15 to $32 in 1917, $11 to $16 in 1916, and $14 to $16 in 1914 and 1915. It is interesting to know uses to which imported kaolin are put and the following estimates by uses have been made: Paper, 60 per cent; pottery, 25 per cent; paint, 3 per cent; tile, 2 per cent; oilcloth, 4 per cent; and miscellaneous uses, 6 per cent. Clays imported under the name of common blue and Gross-Almerode glasspot clays came principally from Germany, and hence have declined from 24,986 tons in 1913 to nothing in 1918, the negligible quantities reported for 1917 and 1918 probably coming from England.

Unwrought clay, which is believed to be principally English ball clay, increased slightly in quantity—403 tons—but increased $40,045, or 32 per cent, in value.

EXPORTS.

Exports of clay have been reported separately only for a few years. Fire clay is the chief kind exported. In 1918 it constituted 71 per cent of the quantity exported and 63 per cent of its value.

Clay exported from the United States, 1916–1918.

Year.	Fire clay.		All other.		Total.

SILICA BRICK.

PRODUCTION.

The production of silica fire brick has made wonderful progress in the last nine years, as is shown in the following table:

Silica brick produced in the United States, 1910–1918.

Year.	Quantity (thousands).	Value.	Average price per thousand.
1910	145,779	$3,289,028	$22.56
1911	104,483	2,520,816	24.13
1912	135,578	2,923,174	21.56
1913	174,246	3,815,806	21.90
1914	129,693	2,951,525	22.76
1915	130,244	3,039,869	23.34
1916	232,673	6,369,256	27.37
1917	327,030	15,510,595	47.43
1918	336,562	19,987,803	59.39

In 1918 silica brick was produced in 13 States, an increase of 2 compared with 1917. Maryland, New Jersey, and Washington, which reported no silica brick in 1917, entered the list of producers in 1918 and Kentucky reported none. The States reporting silica brick for 1918 were: Alabama, California, Colorado, Illinois, Indiana, Maryland, Missouri, Montana, New Jersey, Ohio, Pennsylvania, Utah, and Washington. As there were three producers or more in only two States, Ohio and Pennsylvania, totals for these States only can be given. Pennsylvania was the leading State in 1918, as it had been throughout the period covered by the table, and it reported 233,143,000 9-inch equivalent brick, valued at $13,352,687, or 69 per cent of the total output and 67 per cent of the total value. The output in Pennsylvania increased 10,100,000 brick, or nearly 5 per cent, and the value increased $2,933,142, or 28 per cent, compared with 1917. Illinois was second and Indiana third in rank. These three States reported 91 per cent of the total output and value in 1918. Ohio was fourth with an output of 7,161,000 brick, valued at $386,179.

The output increased during this period from a minimum of 104,483,000 brick, valued at $2,520,816, in 1911 to 336,562,000 brick, valued at $19,987,803, in 1918, an increase of 232,079,000 brick, or 222 per cent, in quantity, and of $17,466,987, or 693 per cent, in value. The increase in 1918 compared with 1917 was 9,532,000 brick, or 3 per cent, in quantity, and $4,477,208, or 29 per cent, in value. The rapid rise in the output and value of this material, especially in the last few years, may be ascribed to the war, which increased the demand for iron and steel and coke-oven by-products, in the making of which silica refractory brick finds its chief use.

The Bureau of Standards, of the Department of Commerce, has recently issued a very comprehensive report[1] on this subject, from which the following extracts are taken:

The following remarks describe the general method of manufacture at a plant which uses Pennsylvania Medina quartzite. Most other silica-brick plants in the United States follow approximately this procedure except as noted below.

The rock direct from the quarry is crushed to pass through a 2-inch ring. Washing of the rock to remove foreign or earthy matter may be resorted to at certain places. The material is then taken in a car to the wet pan and there dumped. Each charge for a pan weighs about 1,250 pounds. A little water is added and the material is ground for 15 minutes. After 10 minutes of this grinding, 2 per cent of lime by weight is added as slaked high-calcium lime, in the form of a thin slip. It is run through a

[1] Ross, D. W., Silica refractories: Bur. Standards Tech. Paper 116, 1919.

spout to the middle of the crushing surface of the pan, while the pan is in motion. * * * In this way the lime is thoroughly mixed with the quartzite. When the grinding has continued for the full 15 minutes the mix is ready for molding and is removed from the pan to a tramcar by means of a mechanical scraper.

The lime is prepared by weighing out enough quicklime to furnish exactly 2 per cent of CaO to the weight of quartzite. The weighing out is done on the basis of an analysis. Thus, if the lime contains only 90 per cent CaO, proportionately more is added. This lime is then placed in a small mixer or blunger; is slaked and stirred up to the proper consistency; and then run through a screen of approximately 10 meshes per linear inch on its way to the wet pan. Hydrated lime is sometimes weighed into the mixer instead of quicklime and appears to give exactly the same results.

From the pan the mix is carried to an elevator, raised to an upper floor, and dropped into a container, from which the workmen use it directly in filling the brick molds. This container is in the nature of a cylinder approximately 5 feet in diameter and 10 to 15 feet tall, with slatted openings at the bottom, so that the material can be removed readily. The slats can also be removed. The molders work at benches adjoining the outlets of the containers. The brick molds are of iron and consist of a bottom plate on which lies a 3-brick form. The brand on the brick is formed by the bottom plate of the mold. Directly above the molds is situated a screen, which can be shaken by the operator. Pennsylvania washed glass sand is placed upon this screen, and a slight jar is sufficient to shake down enough sand to sand a set of molds.

* * * A mass of mix is wadded together with the hands and is then thrown heavily into the molds and rammed in, the surplus struck off, and the bricks turned out on an iron pallet. These pallets are then placed on drier cars. When a car is full it is left standing in the open for a few minutes and is then run into a hot-air drier. Regular burn brick are made up just wet enough so that they will fill the corners of the molds readily. The mix for large shapes is made slightly drier than for regular brick, but the grind is longer, approximately two or three pans per hour instead of four. (The grind for regular brick is at the rate of four pans per hour.) This extra grinding aids in producing a more plastic consistency. The material for large shapes is pounded into the molds with heavy wooden mallets. As the jars due to the plant engines and passing trains tend to cause large shapes to deform before they get their initial set, the stiffer they are when they come from the mold, the better.

Of course the time of grinding at each plant will depend somewhat upon the nature of the quartzite used and the ware being turned out. Some plants make up brick as described above, and when the bricks are partially dry they are re-pressed. Another way is to have the mix somewhat drier to start with and make the brick up directly on a dry press machine.

Practically all types of driers used for drying heavy clay wares have also been applied to drying silica wares. Perhaps the most satisfactory type from an economical standpoint is a Richardson type tunnel drier, using waste heat from cooling kilns, and if necessary an auxiliary heater, either a small furnace and brick checkerwork, or else by passing air over exhaust steam pipes. Silica brick give practically no trouble in drying. The only requirement is that the brick must be bone dry before being set in the kilns. Otherwise, they break under the pressure when set, or tend to slump and break during water smoking.

* * * The kilns are of the regulation circular down-draft type, varying from 30 to 40 feet in diameter. The bag walls are usually low, as direct fire does not appear to affect the brick much. Regular 9-inch silica brick are set approximately 3 to 3½ on 1, or, in other words, ½ inch is left between the bricks to allow for expansion. They are put in benches 4 feet wide by the width of the kiln by the height of the kiln, and a space of 4 inches is left between benches, and approximately 18 inches between the top of the bench and the crown of the kiln. This latter is done to prevent lifting of the crown of the kiln by the expanding brick. Thus, the benches are from 12 to 15 feet high. As set in the kilns there is a pressure of approximately 15 pounds per square inch on the bottom brick, which do not crush or crack if they are thoroughly dry. A course of bats is put in occasionally to level up the bench horizontally, but they are not used in any way to take the load off the unburned brick. In general the time of burning is nine days, with a maximum heat treatment equivalent to cone 14–18. Five to eight additional days are required for cooling.

A departure from the usual method of burning, which is used by some plants, is the continuous-tunnel kiln. With these kilns the period of burning is approximately a week, and the cooling takes another week. The maximum heat treatment is equivalent to cone 12–14.

In England and other European countries brick which contain 96 per cent or more of SiO_2 are manufactured in a manner similar to that used for making silica brick in the United States, except that the methods of mixing, etc., vary somewhat. It is a frequent custom in England to use a somewhat lower percentage of lime (1.3 per cent or even less) and add a small precentage of a highly siliceous clay to strengthen the brick in the raw state. If clay were not added to these brick, they would be weak because of their low lime content.

In England segmental gas retorts are frequently made from materials which contain 85 to 92 per cent of SiO_2. Such pieces are, of course, made by mixing larger percentages of siliceous clays with the silica, and hence do not correspond to silica brick as manufactured in the United States.

USES IN INDUSTRIES.

Silica refractories are particularly useful in industrial work. This is due to their rigidity at temperatures above the range of usefulness of ordinary fire-clay brick and to the fact that they expand slightly when heated instead of shrinking as clay brick do.

For by-product coke-oven work the brick in the regenerative and lower two-thirds of the coking chamber should have a high fusion point, as an extreme temperature of 1,510 to 1,540° C. is sometimes reached. The brick in the lower two-thirds of the coking chamber, where they come in contact with the coal and coke during charging and unloading, must also resist abrasion. The upper one-third of the coking chamber may be made of lower fusion point material and need not be particularly resistant to abrasion, as here the temperature rarely exceeds 1,320° C. and the brick are seldom touched by coal or coke. Occasionally charges of coal have been found to expand in the coking chambers, so that when coked they could not be removed by the usual mechanical device. Trouble from cracking and spalling may sometimes occur if the ovens are heated up too rapidly. However, when the temperature of a series of these ovens is once raised to the operating temperature, they should last for years, except for repairs occasioned by abrasion, etc.

From the work of Blasberg [1] we gather that silica refractories which have been used in Siemens by-product coke ovens frequently show an increase in iron and always a considerable increase in alkalies, particularly the brick used in the checkerwork. In many cases they contain up to 1 per cent of carbon. It is assumed that the carbon comes from the dissociation of gaseous hydrocarbons or carbon monoxide, and that the other contamination comes from the coal ash. The conclusions drawn are that for this work silica brick should be as low in porosity as possible and that the gases should be free from flue dust.

In open-hearth steel furnace work, silica brick are used for the top, ends, and sometimes for the side walls of the furnace. Here the chief essentials are that the brick have a high crushing strength when hot and high resistance to spalling and slagging, as well as high softening temperature.

The port bulkheads at the ends of these furnaces are subjected to a severe sand-blast action from particles of limestone and iron oxide, which are blown over from the hearth of the furnace. As these materials both act as active fluxes on silica brick under reducing conditions, the result is that these bulkheads are rapidly eaten away by a combined cutting and slagging action. The 13-inch brick used in these bulkheads wear away so fast that it is frequently necessary to replace them in two or three weeks. Crowns of such furnaces are also somewhat attacked by the slagging action of lime and iron oxide which are blown up against them and also by the dust of the gaseous fuel used. Thus, an average crown lasts approximately 300 heats when natural gas, which is quite free from dust, is used as a fuel; approximately 200 heats with producer gas, which contains considerable dust; and somewhat less than 200 heats when powdered coal is used.

For steel furnace work it is desirable that the softening temperature (as described below) of the brick be somewhat above that of Orton cone No. 31. Even then, at times the surface of the bricks will melt and hang down in long white stalactite-like forms from the crown of a furnace.

The uses of silica refractories in copper reverberatory furnaces are similar to those in open-hearth steel furnaces, except that for melts of lead-free metallic copper, silica can be used throughout the furnace except at the slag line. For this work the brick should be as low in porosity as possible to avoid absorption of copper oxide. which slags away the bricks when the furnace is at its maximum temperature, Silica brick arches in copper furnace work wear much better if they are not insulated.

[1] Stahl u. Eisen, vol. 30, pp. 1055-1060; 1910.

The maximum temperature reached in the copper refining furnaces is approximately 1,350° C.; hence, for this purpose some refractoriness might be sacrificed if anything is to be gained thereby in decreased porosity and resistance to spalling.

In glass furnace work silica refractories are used for furnace roofs, and are useful for stiffening up walls, etc., made of clay brick, which would otherwise soften and sag from the effect of heat and fumes arising from the glass.

BUILDING OPERATIONS.

The accompanying tables show the building operations in 1918 in some of the larger cities of the country as indicated by reports obtained from their building departments. Efforts were made to obtain detailed information from 150 cities. Sufficient detail was received from 132 to permit their inclusion in a table showing classes of buildings, but 11 reported only the total number of permits or buildings and the cost of the buildings, and 7 furnished no data.

Statistics of building operations have been collected by the United States Geological Survey only from cities that had a population of 35,000 or more at the last Federal census; none were obtained from the smaller cities or rural communities, from which, so far as known, no effort has ever been made to collect such statistics, as the absence of building regulations in them makes it impracticable.

The table on page 929 makes a comparison between 1917 and 1918 for 58 cities, Greater New York being considered one city. The figures show, as was to be expected, that in most of the cities there was a large decrease in the number and cost of buildings in 1918 compared even with 1917, which showed a large decrease from 1916. The decrease in these cities in 1918 compared with 1916 was $557,647,911, or 61 per cent, and when it is remembered that higher prices increased the cost of the operations in 1918 as compared with the cost of those of 1917 these decreases assume added significance.

The outlook for 1919, notwithstanding the high cost of material and labor, appears to be good, not only because buildings of all kinds are imperatively needed but because it is realized that there is no prospect that costs will be lowered; further, the reports received indicate that building operations throughout the country are rapidly assuming normal proportions and that not only cost will be much greater in 1919 than in 1918, but that the number of operations will also show a large increase. The building industry now has a double opportunity—it may be able to relieve unemployment and at the same time to provide homes, shops, factories, and offices that are in many places sorely needed.

Of the 58 cities given in the first table 48 showed decrease and 10 showed increase in the total cost of building operations. Only one of the cities included in this table—Youngstown—showed increase in both 1917 and 1918. Nine of the cities that increased in 1917 decreased in 1918—Akron, Ohio; Atlanta, Ga.; Denver, Colo.; El Paso, Tex.; Hartford, Conn.; Los Angeles, Calif.; New Haven, Conn.; Sioux City, Iowa; and Waterbury, Conn.; and nine cities that decreased in 1917 increased in 1918—Camden, N. J.; Des Moines, Iowa; Jersey City, N. J.; Louisville, Ky.; Oakland, Calif.; Portland, Oreg.; Providence, R. I.; St. Paul, Minn.; and Seattle, Wash. Thirty-nine cities showed decrease in both years. Two cities—Chester, Pa., and Omaha, Nebr.—have not reported for 1918, and they are therefore not included in the table.

The largest decrease was in Greater New York. The next four cities, Chicago, Detroit, Cleveland, and Philadelphia, also showed large decreases.

Various reasons are given for these changes. The dominant reasons for the decreases are the restriction of the use of building materials by the Government to necessary war work and the scarcity and high cost of materials and labor. The causes for the increases are the excessive cost, due to the high price of labor and materials, and the increase in operations in the centers of Government building activities, such as Camden, N. J., Portland, Oreg., Providence, R. I., and Seattle, Wash. The construction and occupation of the army camps and cantonments probably had a stimulating effect on the building industries in the neighboring cities, although Des Moines, Iowa, near which Camp Dodge was located, reported that the increase in that city was due chiefly to the erection of two large hotels and a municipal courthouse. It is quite conceivable, however, that the demand for the hotels was caused, to some extent at least, by the proximity of the camp.

The cost of building operations in these cities in 1918 ranged from $469,423 in Newton, Mass., to $53,602,004, in Greater New York, and the average for these 58 cities was $6,099,183, compared with $10,104,531, in 1917, and $15,713,802, in 1916. The number of permits issued or buildings erected in 1918 in these cities was 46,208 less than in 1917, and 117,546 less than in 1916.

In addition to the general building operations, vast building operations were carried on by the United States Government in 1917 and 1918, principally in army cantonments and camps and navy yards and docks. The United States Housing Corporation erected buildings in 28 cities. The Government, through the office of the Supervising Architect, carried on building operations in 27 cities; the Emergency Fleet Corporation erected houses at a number of places for the accommodation of its employees; the Navy Department conducted building operations in 41 places. In the aggregate they involved a very large expenditure of material and money. Complete information concerning all these expenditures is not yet available.

It has been impracticable to report the expenditures by the Construction Division of the War Department either by calendar years or by character of construction. The allotments for the fiscal year 1918 for construction work of all kinds for the Army, including public utilities, was $420,259,162. This work included 16 National Army camps, 16 National Guard camps (in which 43,234 buildings were constructed), embarkation camps, camps for artillery, Engineer Corps, Motor Transport Corps, work on coast defenses, Quartermaster Army supply bases, depots, and warehouses, hospitals,. ordnance depots, proving grounds, and regular Army posts. In March, 1918, at the time of the reorganization of the Construction Division, emergency work costing $600,000,000 was in prospect for munitions factories, storage warehouses, hospitals, port terminals, and interior depots in all parts of the country.[1] Some of this was covered by the $420,259,162 already mentioned. In addition, during the first half of the fiscal year 1919 (July 1 to December 31, 1918) many more millions of dollars was spent by the War Department in the construction of buildings at camps and elsewhere, so that it seems safe to

[1] Report of the Chief of the Construction Division to the Secretary of War, 1918, p. 33.

estimate that from July 1, 1917, to the end of 1918 the sum of $1,000,000,000 was spent by the War Department for structural work. If to this sum is added the cost of other Government work in 1918—$102,960,977—it will be seen that after allotting a large proportion of the expenditures of the War Department to non-structural work the cost of building operations of the Government largely offset the loss in general building operations.

Building operations in the leading cities of the United States in 1917 and 1918.

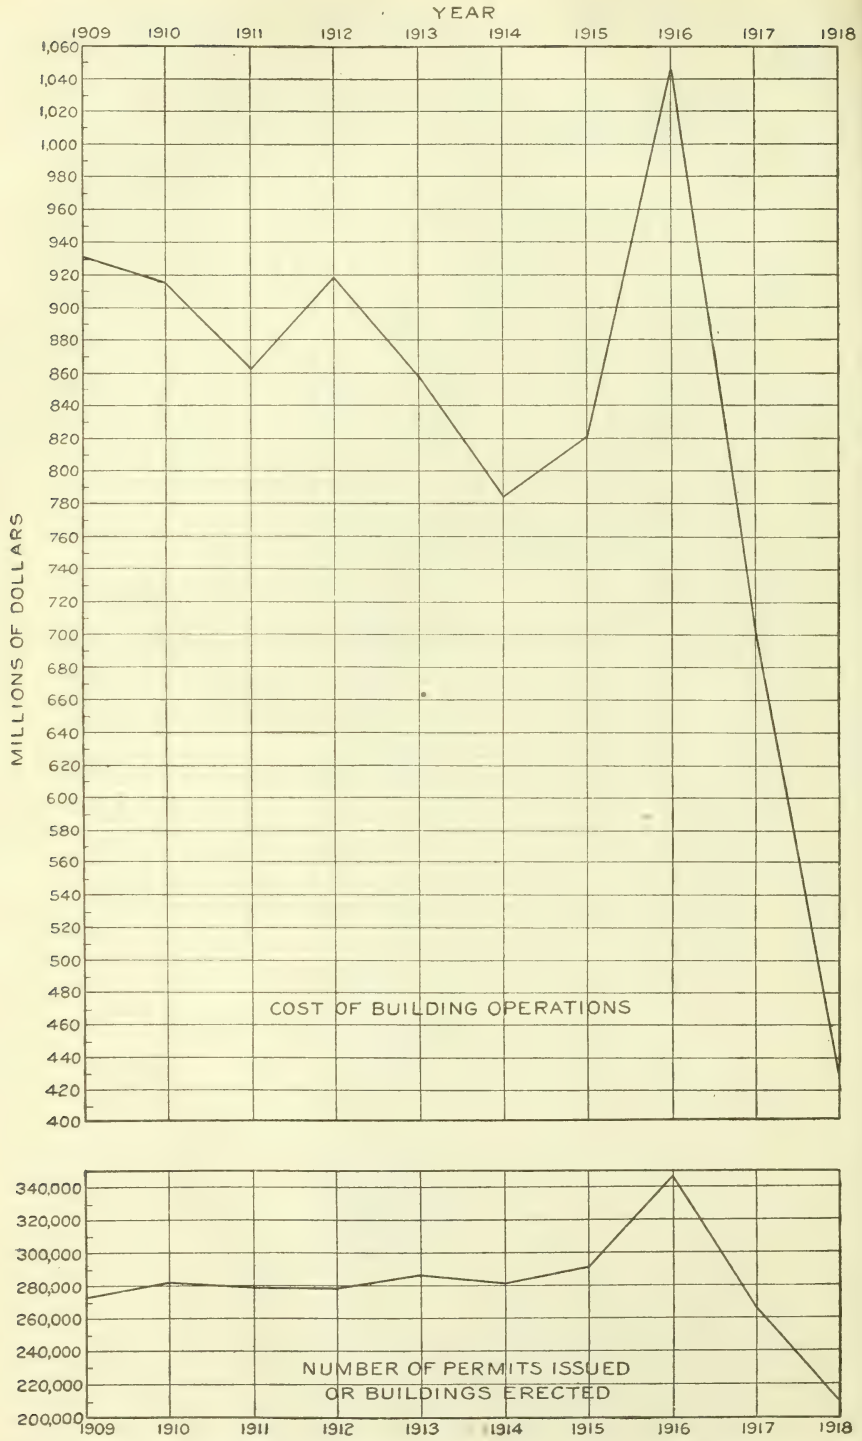

FIGURE 98.—Diagram showing building operations in some of the larger cities of the United States, 1909–1918.

The statistics given in the following table are shown graphically in figure 98.

Building operations in the larger cities of the United States, 1909–1918.

Year.	Number of cities.	Number of permits or buildings.	Cost.	Average cost per permit or building.
1909	137	273,883	$930,520,713	$3,398
1910	145	282,661	916,353,775	3,242
1911	145	279,017	863,968,860	3,096
1912	143	278,129	919,809,054	3,307
1913	147	285,850	859,657,250	3,007
1914	147	281,174	785,525,746	2,794
1915	144	292,707	821,120,657	2,805
1916	146	347,761	1,046,276,549	3,009
1917	145	266,686	700,700,815	2,627
1918	143	210,538	430,014,365	2,042

The 143 cities included in the accompanying tables reported building operations costing $430,014,365 in 1918. Practically the same cities reported building operations costing $700,700,815 in 1917, and $1,046,276,549 in 1916, a decrease of 39 per cent compared with 1917 and of 59 per cent compared with 1916. The average cost per operation in these 143 cities in 1918 was $2,042, the lowest in ten years, and was 40 per cent lower than the maximum of 1909.

Of this number 132 cities reported sufficient detail to permit the publication of statistics of operations by classes of structures. These cities reported 200,786 permits or buildings that cost $372,955,028. Of this amount new operations of every kind, represented by 81,516 permits or buildings, cost $269,750,562, or 72 per cent of the total; additions, alterations, and repairs, represented by 95,196 permits or buildings, cost $85,699,971, or 23 per cent of the total; and miscellaneous operations, represented by 24,074 permits or buildings, cost $17,504,495, or nearly 5 per cent of the total. In 1917 practically the same cities reported 247,954 permits or buildings, costing $645,980,162, of which 105,018 operations for new work, cost $530,416,779, or 82 per cent of the total; additions, alterations, and repairs, represented by 101,094 permits or buildings, cost $92,434,292, or 14 per cent; and 41,842 miscellaneous and undistributed operations cost $23,129,091, or 4 per cent.

The statistics of building operations by kinds, especially the totals, are only approximate, for many cities were unable to report strictly in accordance with the classification given in the table, but it is believed that the figures published are accurate enough to give a good idea of the relative importance of the various kinds of operations enumerated.

The rank of the several cities in the different classes of building operations is relative, not actual, as the expenditures in some cities that reported no details may have exceeded those in some cities that reported the cost of buildings by classes.

Taken by classes the new wooden buildings in these 132 cities in 1918 cost $89,786,648, or 24 per cent of the total; new brick or hollow tile buildings cost $134,628,524, or 36 per cent of the total; new stone buildings cost $3,840,978, or 1 per cent of the total; new concrete buildings cost $28,299,309, or 8 per cent; and new steel skeleton buildings cost $13,195,103, or nearly 4 per cent. Of the new buildings those constructed of wood cost 33 per cent of the total for new buildings; new fire-resisting buildings cost $179,963,914, or 67 per cent; those of

brick or hollow tile, 50 per cent; those of stone, 1 per cent; those of concrete, nearly 11 per cent; and steel skeleton buildings, 5 per cent.

Of the cost of all additions, alterations, and repairs, $27,428,361, or 32 per cent, was for wooden buildings. Additions, alterations, and repairs to fire-resisting buildings cost $58,271,610, or 68 per cent. Of the fire-resisting buildings, additions to brick or hollow tile buildings cost $48,862,366, or 57 per cent; those to stone buildings cost $2,478,671, or 3 per cent; those to concrete buildings, $3,780,096, or 4 per cent; and those to steel skeleton buildings, $3,150,477, or 4 per cent.

The cost in these cities of all operations on wooden buildings was $117,215,009, or nearly 32 per cent of the total cost of all building operations; brick or hollow tile buildings, new and additions, alterations, and repairs, cost $183,490,890, or nearly 50 per cent; stone buildings $6,319,649, or nearly 2 per cent; concrete buildings $32,079,405, or nearly 9 per cent; and steel skeleton buildings $16,345,580, or 4 per cent of the total.

The decline in the erection of new buildings and the tendency to economize by an increased resort to alterations, additions, and repairs are shown by the following table:

Percentage of cost of different classes of building operations in 132 cities, 1917 and 1918.

	1917	1918
New construction	82	72
Alterations, additions, and repairs	14	23
Miscellaneous, including undistributed operations	4	5

FELDSPAR.

By L. M. Beach.

PRODUCTION.

There was a decrease of approximately 30 per cent in the quantity of feldspar marketed in this country in 1918, as compared with 1917. The industry was showing a healthy growth in 1916 and 1917 and during the early part of 1918, but later in the year the exigencies of war caused production to decrease. The main causes of the decrease were the scarcity of labor, the curtailment of fuel supply to the pottery industry, which was deemed nonessential, and shortage of railroad service. This decline in production was partly compensated by higher prices.

Figure 99.—Diagram showing annual output of crude feldspar, 1907–1918.

Crude feldspar sold for an average price of $4.65 a long ton in 1918; the average price in 1917 was $3.40 a ton, and in 1916 it was $3.34. The range of prices in 1918, according to reports received by the United States Geological Survey, was from $1.75 to $10.50 a long ton; in 1917 the range was from $2 to $7 a ton. Ground feldspar was marketed at an average price of $12.33 a short ton, compared with $10.15 in 1917 and with $9.30 in 1916. The reported range of prices for ground feldspar in 1918 was from $4.76 to $18 a short ton; in 1917 it was from $5.70 to $17 a ton.

Of the total production in 1918, 68 per cent was sold crude and 32 per cent ground; in 1917, 70 per cent was sold crude, and in 1916, 63 per cent. North Carolina is credited with the production of a certain quantity of feldspar which is ground in Tennessee before it is sold. The total quantity of ground spar sold in the United States in 1918 was approximately 32,000 short tons.

Producers of feldspar sell the crude material by the long ton. The following table shows the quantity of feldspar produced in each State whether first marketed as crude or ground spar, but the value given is an estimated average for crude spar in each State.

Feldspar sold in 1917 and 1918, and value at price for crude feldspar.

State.	1917		1918	
	Quantity (long tons).	Value.	Quantity (long tons).	Value.
California	7,031	$18,137	1,296	$8,839
Connecticut	a 10,455	a 43,160	5,305	29,419
Maine	31,720	131,994	22,656	105,430
Maryland	14,088	56,958	7,843	40,299
New York	12,019	44,290	11,277	58,076
North Carolina	42,463	131,442	35,732	160,275
Pennsylvania	8,939	48,786	4,389	27,651
	126,715	474,767	88,498	429,989

a Includes New Hampshire.

Many feldspar miners grind their spar and market it in the ground form and by the short ton; hence the following table is given in short tons. The quantities given in this table are the same as in the preceding table, converted from long to short tons. The values for each State, however, are the sum of sales of both crude and ground spar and represent the money actually paid for the spar when first marketed.

Crude and ground feldspar sold in 1917 and 1918.

State.	1917		1918	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.
California	7,874	$18,543	1,451	$8,839
Connecticut	a 11,710	a 77,432	5,942	52,117

a Includes New Hampshire.

FELDSPAR INDUSTRY, BY STATES.

The sales of feldspar in 1918 were reported from the following States, named in the order of their output: North Carolina, Maine, New York, Maryland, Connecticut, Pennsylvania, and California; named in order of the value of their output the States were Maine, North Carolina, New York, Pennsylvania, Connecticut, Maryland, and California.

California.—Six quarries, operated by six separate firms, three located in Tulare County, two in Riverside County, and one in Monterey County, reported production in 1918, as against 10 quarries operated by eight firms, working four in Riverside County, and one each in Tulare, San Bernardino, Monterey, and Los Angeles counties in 1917. The production in 1918 amounted to 1,296 long tons of crude product, valued at $8,839. The figures for 1917 were 7,031 long tons, valued at $18,137. Crude feldspar sold for $4 to $7 a long ton in California at the quarries; pottery grades averaged about

$6.95. The pottery grades sold for $4.50 a long ton in 1917, and the crude ranged between $2 and $7.80 f. o. b. quarries.

Connecticut.—In 1918 three Connecticut firms reported feldspar production, two operating in Hartford and Middlesex counties, and one at Willimantic, in Windham County. As in 1917 there was a decrease, only 5,305 long tons of crude product, valued at $29,419, being produced. This feldspar was used chiefly in pottery and enameling, the remainder selling for use in abrasives and scouring soaps. The quantity of crude feldspar produced in Connecticut in 1917 was larger, but the unit prices were much below those obtained in 1918. The prices on crude spar ranged in 1918 between $5.96 and $10.50 a long ton f. o. b. quarries; the range in 1917 was between $4 and $7. Ground feldspar brought from $10.50 to $20 a short ton f. o. b. mills in 1918, whereas in 1917 the prices ranged from $8.90 to $17.

Delaware.—Wilmington is a very important feldspar market, and several grinding mills are located there. There was no production of feldspar in Delaware in 1918.

Maine.—Maine ranked second in output and first in value of feldspar produced in 1918. The number of operators reporting production in 1918 was five, as compared with six in 1917, and the number of active quarries decreased from nine to seven. The total output of feldspar in 1918 was 22,656 long tons of crude, valued at $105,430, a decrease in both quantity and value from the preceding year, when 31,720 long tons produced sold for $131,994. The Maine Feldspar Co., operating mills at Topsham, in Sagadahoc County, and at Auburn, in Androscoggin, and the Trenton Flint & Spar Co., at Cathance, Sagadahoc County, produced and sold most of the State's output. In 1918 prices of crude feldspar ranged between $4.25 and $5.80 a long ton, as compared with $3 and $4.50 received in 1917; and prices of ground feldspar were $12.28 to $14 in 1918, against $11 to $11.30 in 1917. A large portion of the output in 1918 went to the pottery trade; some was used in the preparation of ceramic binders for carborundum and corundum grinding wheels; and a small portion went into the manufacture of abrasive soaps.

Maryland.—Ten operators in Maryland reported production in 1918, an increase of three over 1917. Notwithstanding this, however, the State dropped from third to fourth place in the quantity of spar produced. The output in 1918 amounted to 7,843 long tons of crude spar; prices ranged from $4 to $6.16 a long ton and averaged $5.14 f. o. b. quarries; in 1917 there were 14,088 long tons produced, which sold at $3 to $4.50 a long ton and averaged $4.04 f. o. b. quarries. The principal quarries are located in Baltimore, Howard, Carroll, and Cecil counties.

New Hampshire.—No feldspar was quarried in New Hampshire in 1918, although in previous years this State had been an active producer, its spar going into the manufacture of scouring soaps.

New Jersey.—Trenton is an important feldspar market and the location of several grinding mills. There are no deposits in New Jersey.

New York.—New York was an active producer of feldspar in 1918 and ranked third among the producing States of the Union instead of fourth as in 1917. In the value of its yield New York rose from fifth place in 1917 to third place. The output was 11,277 long tons

of crude feldspar in 1918, as against 12,019 long tons in 1917. This slight decrease was counterbalanced by the good prices prevailing, the output in 1918 selling for $58,076, as compared with $44,290 in 1917. Pottery spar in the crude sold for $3.92 to $6 a long ton in 1918, as compared with $3 to $4.50 a ton in 1917. Crude feldspar sold for an average price of $4.60 in New York in 1918, against $3.05 in 1917, and ground feldspar sold for $8 in 1918, as compared with $7.04 in 1917.

Three companies, located in Essex, Westchester, Monroe, and St. Lawrence counties, reported operations in New York. The greater portion of the output of spar was consumed as roofing, concrete facing, and chicken grits, the remainder going into enamel ware and pottery products.

North Carolina.—North Carolina ranked first in quantity and second in value of its production in 1918, although only 10 quarries reported operations during the year, compared with 24 in 1917. The principal operations were confined to Mitchell, Avery, and Yancey counties. The output of crude feldspar in 1918 was 35,732 long tons, valued at $160,275, as against $131,442 received in 1917 for 42,463 long tons. Prices ranged from $2 to $6 a ton, the prevailing price was $4.50, and the average was $4.49. In 1917 the range was between $2.60 and $7 a ton, the prevailing price was about $4, and the average price was $3.10. As in 1917, much of the product in 1918 was ground at Erwin, Tenn., and the remainder went to the mills at East Liverpool, Ohio, and Trenton, N. J.

Pennsylvania.—Pennsylvania ranked sixth in quantity and fourth in value of production of feldspar. Three producers reported activity during 1918 as compared with 10 in 1917. The spar was taken from three large quarries and a number of smaller ones in Chester and Delaware counties. The total production was 4,389 long tons of crude spar, valued at $27,651 f. o. b. mines. There was 8,939 long tons mined and sold in 1917, valued at $48,786. The greater part of the output in 1918 was quarried at Brandywine Summit and Toughkenamon. Prices for crude spar averaged $5 a ton in 1918, a few cents less than the average in 1917. Ground feldspar sold from $8.58 to $18, and averaged $12.45 a ton in 1918; in 1917 the range was between $7.20 and $12, and the average was $10.25. Feldspar is used principally in Pennsylvania in the manufacture of glassware, pottery, abrasive soaps, and chicken grits.

Vermont and Virginia.—No production of feldspar was reported either in Vermont or Virginia for the year 1918.

FELDSPAR IN CANADA.

The following tabulation chronicles the feldspar industry activities in Canada in 1918 and other recent years. The United States imports practically all of the Canadian product, although it does not import feldspar from any other country.

Feldspar sold in Canada, 1913–1918.[a]

Year.	Quantity (short tons).	Value.	Year.	Quantity (short tons).	Value.
1913	15,935	$56,841	1916	19,488	$71,407
1914	18,060	70,824	1917	11,493	54,555
1915	15,455	59,124	1918[b]	20,232	117,379

[a] Statistics taken from reports on the mineral production of Canada, Canada Dept. Mines.
[b] Figures for 1918 preliminary and subject to revision.

FELDSPAR MILLS.

Exclusive of mills operated by feldspar consumers for grinding spar for their own use, there are mills in the Eastern States operated by the following firms, dealers in feldspar, at the places named: Maine Feldspar Co., Auburn and Topsham, Maine; Trenton Flint & Spar Co., Cathance, Maine; Louis W. Howe, South Glastonbury, Conn.; Bedford Mining Co., Bedford, N. Y.; Pennsylvania Feldspar Co., Barnard, N. Y., and Toughkenamon, Pa.; Brandywine Summit Kaolin & Feldspar Co., Brandywine Summit, Pa.; Eureka Flint & Spar Co., Trenton, N. J.; Golding Sons Co., Trenton, N. J., Wilmington, Del., and East Liverpool, Ohio; Potters Mining & Milling Co., East Liverpool, Ohio; Newell Mining & Pulverizing Co., Newell, W. Va.; Clinchfield Products Corporation, Erwin, Tenn.; and Rochester Feldspar Mills (Inc.), Rochester, N. Y.

USES.

Most of the high-grade feldspar is used in the manufacture of ceramic products; it is also used as an abrasive in the manufacture of scouring soaps and window wash. A small quantity of the purest material is used in making artificial teeth.

The lower grades of feldspar are used as a binder in the manufacture of emery and corundum wheels, in the manufacture of glass, in roofing material, and for concrete work.

BIBLIOGRAPHY.

The following publications treat of the distribution of domestic feldspar deposits:

Bastin, E. S., Economic geology of the feldspar deposits of the United States: U. S. Geol. Survey Bull. 420, 1910.

——— Geology of the pegmatites and associated rocks of Maine: U. S. Geol. Survey Bull. 445, 1911.

De Schmidt, H. S., Feldspar in Canada, Canada Dept. Mines, Mines Branch, Ottawa, 1916. This recent illustrated publication describes deposits of feldspar in Canada, the United States, Australia, and European countries and contains useful chapters on mining, preparation, and uses of feldspar and a bibliography of feldspar technology.

BARYTES.

By George W. Stose.[1]

CRUDE BARYTES.

PRODUCTION.

In 1918 the domestic crude barytes marketed in the United States amounted to 155,368 short tons, valued at $1,044,905. This marks a steady decrease in sales since the climax was reached in 1916, when nearly 222,000 tons was sold. (See table below.) This decrease was due not so much to a decline in the demand for barium products as to the scarcity and high cost of labor. There was a decrease in 1918 of 25 per cent in quantity from the output in 1917 and of 30 per cent from that in 1916, but the value of the output in 1918 was somewhat greater than that of 1916 and less than that of 1917. The average price per ton increased from $4.56 in 1916 to $5.66 in 1917 and to $6.73 in 1918. The large output in 1916 was about double that of 1915 and more than four times the output of 1914.

Crude barytes produced and marketed in the United States, 1880–1918.

a Included in "Other States."
b Includes, 1916 and 1917: California, Nevada, South Carolina, and Virginia; 1918: Kentucky, Nevada, New Mexico, North Carolina, South Carolina, Virginia, and Wisconsin.

[1] The statistical data in this report were prepared by Miss L. M. Jones, of the United States Geological Survey.

Georgia led all other States in production in 1918, marketing 20,000 tons more than its nearest competitor, Missouri. Georgia's rate of decrease since 1917, its banner year, was 38 per cent, whereas Missouri's rate of decrease was only 17 per cent. Tennessee, the only other State that supplied a considerable part of the production, increased its output about 33 per cent in 1918, although it did not reach its production of 1916, its record year, by nearly 10,000 tons. New Mexico and Wisconsin were added to the producing States, although the quantity marketed by each was small. The production of Kentucky, Nevada, New Mexico, North Carolina, South Carolina, Virginia, and Wisconsin can not be given separately, as there were less than three firms that produced barytes in any one of these States in 1918. The production of each except Kentucky was small, the total sales from these seven States amounting to only 12,620 short tons, or 8 per cent of the total for the United States.

No sale of barytes was reported from California, which was one of the small producers in 1917. Illinois did not market any barytes in 1918 but mined a considerable quantity of this ore with fluorite at mines in the southern part of the State and for the first time successfully separated these ores in a commercial plant. Illinois is therefore expected to enter the producing column in 1919.

STOCKS AT MINES.

In general, barytes is marketed as soon as it is mined, but car shortage and railroad embargoes caused considerable delay in delivery in some parts of the country both in 1917 and 1918 and some operators were unable to market their product promptly. The stocks held at the mines are not included in the preceding table, whereas stocks held by makers of barium products at their mills have entered the market and are included. Apparently about 18,500 short tons of barytes remained in stock in the hands of mine operators on December 31, 1918, as compared with about 20,000 short tons on December 31, 1917. Of this total about 5,700 tons was held by mine operators in Tennessee, 5,500 tons in Missouri, and nearly 4,000 tons in Georgia. This was a decided decrease of stock for Georgia and a large increase for Tennessee, which apparently means that the actual production of Georgia for 1918 was about 2,000 tons less than was marketed and that the production of Tennessee was about 2,000 tons more than was marketed.

IMPORTS.

No barytes was imported into the United States in 1918, and the manufacturers of barium products in this country had to depend for their crude ore entirely on the domestic material. The accompanying table shows how imports declined during the war from 24,423 short tons in 1914 to 17 short tons in 1916 and to none in 1918.

Crude barytes imported for consumption, 1912–1918.

Year.	Quantity (short tons).	Value.	Year.	Quantity (short tons).	Value.
1912	26,186	$52,467	1916	17	$245
1913	35,840	61,409	1917	6	63
1914	24,423	46,782	1918	0	0
1915	2,504	4,877			

This sudden almost complete cessation of imports of barytes in 1915 was caused by the war with Germany, from which most of the foreign barytes has come. The importation of crude barytes from Germany will probably be resumed on a greater scale than before the war, unless discouraged by a tariff. German barytes with a low duty will be much cheaper than domestic ore near the Atlantic seaboard and will probably monopolize most of the eastern trade and cause practically all the mines in the Appalachians to close down. The barium-products industries in the United States, which have greatly expanded during the last few years, will require more raw material than had been mined before the war. The known and readily accessible deposits of barytes in this country are much smaller than those of Germany and more costly to mine, so that it is not reasonable to depend on American deposits for a permanent source of all the barytes needed for the home industries. The tariff of 15 per cent ad valorem, at present in force, will probably not be sufficient to maintain the eastern mines.

MARKETS.

About one-third of the barytes used in the manufacture of barium products in 1918 was ground and floated or otherwise refined and sold as such to manufacturers of paint and other material; almost half was made into lithopone; and the remainder was made into barium chemicals, including blanc fixe, also a paint base. The following table shows the quantities used in these branches of the industry:

Crude barytes used in the manufacture of barium products, 1915–1918, in short tons.

Year.	Manufacture of ground barytes.	Manufacture of lithopone.	Manufacture of barium chemicals.	Total.
1915	53,903	44,503	10,216	108,622
1916	75,507	71,898	38,283	185,688
1917	60,132	86,065	49,842	196,039
1918	62,440	85,282	38,041	185,763

Prior to 1914 the market for crude barytes in the United States centered around two localities—St. Louis, Mo., and Philadelphia, Pa. In the St. Louis district the mineral was used chiefly by manufacturers of ground and refined barytes. In the Philadelphia district some domestic barytes was used also in the manufacture of lithopone, but most of the material used for this purpose was imported from Germany. Since 1914 many lithopone and chemical plants have been established, most of them east of the Mississippi and north of the Ohio, so that the chief markets have remained about the same. But a considerable manufacturing industry has sprung up in the South around Cartersville, Ga., Sweetwater and Johnson City, Tenn., and Charleston, W. Va., and smaller operations have been started in Ohio, Kentucky, and California.

In Missouri much of the mining is done on a small scale by many operators, and their output is bought by agents of one or the other of several large manufacturing companies of St. Louis, Mo., Mineral

Point, Mo., and Chicago, Ill. The J. C. Finck Mineral & Milling Co., of St. Louis, made the largest purchases in 1918, and the Nulsen, Klein & Krausse Manufacturing Co. was the next largest buyer. In the Southern States most of the ore is mined by the larger manufacturing companies for their own use.

PRICES.

The prices obtained for crude ore f. o. b. mines were much higher in 1918 than in 1917 or in any previous year. (See table, p. 951.) The average price received for the total output in the United States was $6.73 per short ton, which is nearly 50 per cent higher than the average price in 1916 ($4.56) and considerably more than double the average price in 1914 ($2.95). The price, however, was not the same in different districts and changed also during the year. The average price for 1918 received by the operators in Missouri was $8.02, and some sales were reported to have brought as much as $10 a ton. The prices obtained in States east of the Mississippi ranged from $4.46 to $7.14 a short ton, the average price in Georgia, the largest producing State, being $6.03.

CONSUMPTION.

The consumption of barytes in the United States can be computed only approximately from the records available, because the stocks on hand at the plants of the manufacturers of the barium products can not be determined. The apparent consumption as stated in the following table is determined by adding the imports to the sales of domestic ore. As there were no imports or exports of barytes in 1918, the apparent consumption is the same as the quantity of domestic barytes sold or used.

Crude barytes apparently consumed in United States, 1912–1918, in short tons.

Year.	Sales of domestic barytes.	Imports for consumption.	Apparent consumption.
1912	37,478	26,186	63,664
1913	45,298	35,840	81,138
1914	52,747	24,423	77,170
1915	108,547	2,504	111,051
1916	221,952	17	221,969
1917	206,888	6	206,894
1918	155,368	0	155,368

The comparison of this table with the table given under the heading Markets, which shows the crude ore used in the various barium-products industries, reveals a discrepancy which represents approximately differences in the stocks of crude ore held by the manufacturers.

BARYTES INDUSTRY, BY STATES.

Alabama.—There was little activity in the barytes industry in Alabama in 1918, only 1,794 short tons being marketed. This was about 200 tons less than was sold in 1917. The ore came chiefly from two mines in Calhoun County and a mine near Centerville, Bibb County. Small quantities were also mined in Shelby County.

Georgia.—The large quantity of barytes marketed in Georgia, amounting to 69,318 short tons in 1918, valued at $418,178, came entirely from Bartow County. Most of it was obtained from seven mines around Cartersville, but about 10,000 tons came from mines near Emerson. Although the State still ranks first in the production of barytes, it lost ground in 1918, its output having declined 38 per cent from that of 1917, which was 111,300 tons. The largest quantity was marketed by the Paga Mining Co., of Cartersville, Ga., which operated three mines but handled only crude ore. All the large plants in the Eastern States that manufacture either ground barytes or lithopone operate mines in Georgia. The Krebs Pigment & Chemical Co., of Newport, Del., operating a mine at Cartersville under the name of the Krebs Mining Co., was the next largest operator, followed in order by the Bertha Mineral Co., mining for the New Jersey Zinc Co., E. I. du Pont de Nemours & Co., of Wilmington, Del., Nulsen, Klein & Krausse Manufacturing Co., Thompson, Weinman & Co., and several smaller operators.

Illinois.—Although no barytes was marketed in Illinois, considerable barytes was mined with fluorspar at Golconda. An attempt had not heretofore been made to separate these two ores, but they are now successfully separated by the use of jigs, and the Illinois product will shortly be put on the market.

Kentucky.—The quantity of barytes marketed in Kentucky in 1918 showed a decline of nearly 10 per cent from the production of 1917. Most of the output came from mines operated by the Central Pigment Co. at Hanly, Jessamine County, and Nicholasville, Woodford County, and was ground in the company's plant at Nicholasville. The mines in Fayette County, from which most of the output came in 1917, were idle in 1918, as were many others in the State. Several mines that changed ownership may be revived later.

Missouri.—The barytes marketed in Missouri in 1918 amounted to 49,094 short tons, valued at $393,738. This compares favorably with the value in 1917 but not with the quantity, which was 59,046 tons. The price received for the ore in 1918 averaged $8.02 a ton, as compared with $6.63 in 1917.

Three-fourths of the ore mined came from Washington County. The quantities marketed by the leading counties were approximately as follows: Washington County, 37,000 short tons; Cole County, 2,700 tons; Jefferson County, 2,100 tons; and St. Francois County, 1,800 tons. Most of the remainder came from Franklin, Miller, and Morgan counties. The largest single producer was the Nulsen, Klein & Krausse Manufacturing Co.'s mine at Cadet, Washington County, and the next largest was the Missouri Lincoln Trust Co.'s mine at Mineral Point, Washington County. As usual, the Nulsen, Klein & Krausse Manufacturing Co. and the J. C. Finck Mineral & Milling Co., both of St. Louis, Mo., and the Point Milling & Manufacturing Co., of Mineral Point, Mo., were the principal buyers of crude barytes from the smaller operators.

A description of the barytes deposits of Missouri and of the geology of the barytes district has recently been published.[1]

[1] Tarr, W. A, The barite deposits of Missouri and the geology of the barite district: Missouri Univ. Studies, vol. 3, No. 1, 1919. Review by G. W. Stose, Econ. Geology, vol. 14, No. 1, pp. 267–269, 1919.

Nevada.—Deposits near Kinkead, Esmeralda County, and Hawthorne, Mineral County, Nev., yielded considerable barytes in 1918, which was shipped to West Berkeley and San Francisco and used in the refined barytes and barium chemical trade.

New Mexico.—The first barytes ore to be marketed in New Mexico was mined in 1918 at Las Cruces, Dona Ana County, and a trial shipment of the ore was sent to El Paso, Tex.

North Carolina.—Not more than 200 tons of barytes was mined in Madison County, N. C., in 1918. Several properties changed hands, and larger production is expected in 1919.

South Carolina.—Deposits at Kings Creek, Cherokee County, S. C., were mined as usual during 1918 by the Cherokee Chemical Co., and the product was ground in its mill at Kings Creek. The output for the State, however, was less than one-fourth of the quantity marketed in 1917.

Tennessee.—Tennessee mines marketed 22,542 short tons of barytes in 1918, valued at $141,844, a great increase over the production in 1917, which was 16,972 tons, valued at $79,058. Sweetwater, Monroe County, was the center of production, and the mines are located in the three adjoining counties of Monroe, McMinn, and Loudon. McMinn County alone sold 9,957 tons. The Durex Chemical Co., whose chemical plant is at Sweetwater, Monroe County, was the largest producer and mined barytes in all three counties.

Virginia.—The deposits at Evington, Campbell County, Va., were actively mined in 1918 by the Clinchfield Products Corporation for use in its chemical plant at Johnson City, Tenn. The quantity produced and used was more than three times that produced in 1917.

Wisconsin.—A small quantity of barytes was mined with lead ore at the lead mines at Cuba, Lafayette County, Wis., and was marketed in 1918. None had previously been produced in Wisconsin, but the output will probably not be large.

DOMESTIC PRODUCERS OF CRUDE BARYTES.

Firms that produced 100 tons or more of barytes in 1918, by States in which mines are situated.

BARYTES DEPOSITS OF THE UNITED STATES.

A brief sketch of the geology and relations of the known deposits of barytes in the United States was given by J. M. Hill in Mineral Resources for 1915 [1] and additional information about newly discovered deposits was given by Mr. Hill in the report for 1916.[2] Only the deposits not heretofore described will be mentioned here.

California.—Large deposits of barytes are reported near Afton, Baxter, and King, San Bernardino County, Calif., on the Los Angeles & Salt Lake Railroad, 50 miles east of Barstow. The deposits have been opened by Massen & Scropian, of San Francisco, who state that they intend to mine the deposit and put up a mill at Afton.

On the west coast of Catalina Island barytes is exposed in an old pit where argentiferous galena was once mined on a small scale. Galena is scattered through a matrix of tabular transparent crystalline barytes, inclosed in Tertiary volcanic rocks.

New Mexico.—A large deposit of barytes is reported near Derry, Sierra County, N. Mex., which has been opened by William Petters and Frank D. Rivera, of Las Cruces. A sample of the ore submitted to the Geological Survey is of high grade, and a sample analyzed by the New Mexico College of Agriculture contained 95.74 per cent of barium sulphate. The barytes is associated with high-grade fluorspar. A carload of the barytes was shipped to El Paso, Tex., in 1918.

Utah.—A large deposit of barytes near Lucin, Boxelder County, Utah, is reported by Frank Edison, of Lucin. A sample of the rock sent to the Geological Survey contained considerable calcite mixed with the barytes.

FOREIGN BARYTES DEPOSITS.

Germany is known to have large deposits of high-grade barytes. The better grade of ore occurs in the Harz Mountains and Thuringerwald, where there are about 150 small surface mines. Ore of poorer grade occurs in the Rhine district. Witherite, barium carbonate, is also mined in the Thuringerwald. Prior to the European war most of the crude ore used in the barium plants of the Atlantic States of the United States was imported from Germany, as were also most of the barium chemicals used in the United States. This ore was mined very cheaply, costing, according to consular reports, from $1.10 to $1.66 a ton at the mine, and crude German ore was

[1] Hill, J. M., Barytes and strontium: U. S. Geol. Survey Mineral Resources, 1915, pt. 2, pp. 166–179, 1916.
[2] Idem, 1916, pt. 2, pp. 246–250, 1918.

quoted for delivery at New York in 1909 c. i. f. (exclusive of duty) at prices ranging from $4.50 a ton for the poorer, grayer rock to $5.50 for the pure-white mineral. As soon as trade relations are again established Germany will probably export large quantities of crude barytes and manufactured products to the United States at prices with which the American producers can not compete unless protected by a tariff.

England has fairly large deposits of barytes and workable deposits of witherite. Before the war England got most of the barytes and barium products for its own use from Germany. Its own mines supplied only a small part of the domestic needs, and no barytes and only a small quantity of witherite was exported to the United States.

Deposits of barytes are known to occur in France, Belgium, Italy, Spain, Portugal, European Turkey, Asia Minor, Tasmania, Australia, and Rhodesia, and although some of them have been extensively worked, the exports from these countries to the United States were small. Deposits in Canada have not been extensively worked, the production in 1917 being only 3,490 short tons and in 1918 640 tons. Since the end of the war, however, inquiries regarding production of barytes and markets in the United States have been received by the United States Geological Survey from several prospective producers in Canada.

Large deposits of barytes are reported at Bueycito, Oriente Province, eastern Cuba, and a test shipment is reported to have been made to lithopone factories in the United States. Samples sent to the United States Geological Survey are of excellent grade, and if the deposits are as large and accessible as reported they may prove to be an important new source for the mineral.

In South America barytes occurs as a gangue mineral in many of the metalliferous veins through the Andes, especially in Argentina, Peru, and Bolivia, but little or no barytes has been separated for shipment.

BARIUM PRODUCTS.

PRODUCTION.

The quantity of ground barytes, lithopone, and barium chemicals sold in the United States in 1918 was slightly greater than that sold in 1917, amounting to 140,675 short tons, and there has been a continued steady growth of these industries in the country since they came into prominence in 1915, as is shown in the following table:

Barium products manufactured in the United States from either domestic or imported crude ore and sold, 1915–1918, in short tons.

Product.	1915	1916	1917	1918
Ground barytes	51,557	65,440	52,694	55,086
Lithopone	46,494	51,291	63,713	62,403
Barium chemicals [a]	8,823	16,792	22,503	23,186
	106,874	133,523	138,910	140,675

[a] Barium chemicals manufactured from secondary barium products bought in open market are not included in table.

GROUND BARYTES.

USES AND PREPARATION.

Barytes is ground for use as a white pigment, as an inert base in colored paints, and as a filler in rubber goods, linoleum, oilcloth, paper, and other articles. When bleached white and ground and reduced to a very fine powder of even texture by the flotation process, it is used largely in ready-mixed white interior paints. The opacity of barytes ground in oil is not so great as that of most other high-grade pigments, so that the covering power of the paint is reduced in proportion to the amount of ground barytes it contains. Barytes is unaffected by acids or alkalies, however, and so does not turn dark on exposure. The pigment is sometimes made to appear whiter by coloring it bluish white by precipitating with it iron sulphate from solution or by adding Prussian or ultramarine blue. Ground barytes is also used as a filler in goods that require a high calendered surface, such as playing cards, white oilcloth, and enameled paper.

In the preparation of high-grade ground barytes the ore is first ground and then bleached with dilute sulphuric acid in lead-lined vats to remove all traces of iron oxide. The German practice of bleaching ore crushed to nut size or larger is not as satisfactory as the American practice of grinding to a meal before bleaching, as it is important to remove all traces of acid if the product is to be used in colored paint or in paper. The crushed and bleached rock is then ground to a fine powder in burr mills or other suitable pulverizers to pass a 200 to 300 mesh screen. The finest grade of ground barytes is obtained by flotation on a stream of water, and this product is called "water floated."

PRODUCTION AND PRICE.

Ground barytes was made and marketed by eight firms in the United States in 1918. Although 2,400 tons more was sold in 1918 than in 1917, the quantity was not so great as that sold in 1916, which holds the record. Of the 55,000 short tons sold, 72 per cent was made in Missouri at plants in St. Louis and Mineral Point. The average price obtained for the Missouri product was $20.42 a ton. Georgia had the next larger production, which was made at Thompson, Weinman & Co.'s plant at Cartersville. Plants were in operation also in South Carolina, Virginia, Kentucky, and California. Two California factories were the only producing plants in the Western States. Although the lowest average price for the year obtained by any plant in 1918 was $12.50 a ton, the average price for the total sales for the year of all plants was $18.91.

Domestic ground barytes in bulk was quoted [1] f. o. b. at the mill at $25 a short ton from July 1 to December 1, 1918, and dropped to $22 a ton in December. Off-color ground barytes in bags in New York ranged in price from $22 to $24 a ton in the early part of the year, rose to $23 to $28 in August, and dropped again to $22 to $24 in December. Pure-white domestic floated barytes in bags was quoted in New York at $28 to $36 a ton from January to April, rose to $33 to $36 at the end of April, and remained at this figure to the

[1] Oil, Paint and Drug Reporter, vols. 93 and 94, 1918.

middle of December, when the price fell to $32 to $34. Foreign prime white barytes ranged from $40 to $50 a ton during January, February, and March, after which there was none to be had.

The companies that reported sales of ground barytes in 1918 are as follows:

Barbour Chemical Works, 707 West Coast Life Building, San Francisco, Calif.; plant at Oakland, Calif.

Central Pigment Co., Strand Building, Forty-seventh Street and Broadway, New York, N. Y.; plant at Nicholasville, Ky.

Cherokee Chemical Co., 109 Hollingsworth Street, Baltimore, Md.; plant at Kings Creek, S. C.

J. C. Finck Mineral & Milling Co., 101 Barton Street, St. Louis, Mo.; plant at St. Louis.

Nulsen, Klein & Krausse Manufacturing Co., Levee and Sidney streets, St. Louis, Mo.; plants at St. Louis and at Lynchburg, Va.

Point Milling & Manufacturing Co., Mineral Point, Mo.; plant at Mineral Point, Mo.

Thompson, Weinman & Co., 100 William Street, New York, N. Y.; plant at Cartersville, Ga.

West Coast Kalsomine Co., West Berkeley, Calif.

LITHOPONE.

USES AND PREPARATION.

Lithopone is a valuable pigment manufactured from barytes and zinc. The process of manufacture is in general as follows: Barytes is chemically treated, and a solution of barium sulphide is obtained. Zinc ore, zinc scrap, or more frequently zinc skimmings and dross from smelters and refineries, is chemically treated, and a solution of zinc sulphate is obtained, which must be purified by the removal of all traces of cadmium, iron, or other metals. These solutions are heated and mixed in a large tank, and the chemical reaction that takes place forms an insoluble precipitate composed of 68 to 70 per cent of barium sulphate and 30 to 32 per cent of zinc sulphide intimately mixed. After the precipitate is dried in filter presses and driers, it is heated red-hot in a furnace and then quenched in water. This is an essential part of the process, for it changes the constitution of the powder by making it more opaque and white, and the grade of the product depends largely on the success of this delicate process.

To insure the complete chemical reaction in the process of precipitation, an excess of barium sulphide, which is both cheap and soluble, is maintained. But this excess must be completely washed out to make the product satisfactory, and this purification is completed in the final grinding in water of the quenched product and floating it.

In the process of drying and heating, some of the zinc sulphide is changed to oxide, so that from 1 to 10 per cent of the finished compound is zinc oxide. Some of the compounds here included under lithopone may have a slightly different composition, their exact contents being kept a trade secret, but they are all believed to be barium-zinc compounds of about the same composition. Lithopone is also mixed with zinc oxide, flake white (lead), or other white pigments in various proportions as pigments, and some of these mixtures that are on the market are also probably included under this heading.

Lithopone is primarily an interior pigment, finding its greatest usefulness as a flat wall paint. Dull-finish wall paint is coming more and more into use on interior walls of buildings and is replacing wall paper in most institutions, such as hotels, hospitals, schools, libraries

and factories, as well as homes, especially where indirect lighting is installed. Lithopone is equal or superior to zinc oxide for this purpose, but for paints having a glazed finish, especially enamels, zinc oxide is more satisfactory. Lithopone can be laid on smoothly though not so smoothly as zinc oxide, and in this respect it is more satisfactory than white lead, which shows brush marks and must therefore be stippled in interior wall work.

Lithopone has many advantages over both white lead and zinc oxide. It is whiter than white lead and equal in whiteness to the best grade of French process zinc oxide. It is not affected by sulphur or hydrogen sulphide as white lead is, and it is nonpoisonous, whereas lead paint is so poisonous that in France and some other countries its use as a paint is prohibited. Lithopone does not blacken by combining with lead contained in pigments or driers with which it is mixed. In opacity or hiding power the pigment is superior to white lead and about equal to zinc oxide, but when it is used in a mixed paint this claim can not be sustained, as the larger quantity of oil used with lithopone reduces its covering power.

As an exterior paint lithopone does not at present give complete satisfaction when used alone, as in direct sunlight it is likely to discolor and turn gray, and its surface becomes chalky and checked. It is claimed that by mixing with lithopone small quantities of other white pigments, such as zinc oxide and whiting (calcium carbonate or chalk), these objections have been removed. Such pigments made in part of lithopone, which are said to be eminently satisfactory for exterior use, are on the market. A mixture of 60 per cent of lithopone, 20 per cent of zinc oxide, and 20 per cent of whiting ground in pure linseed oil has been recommended for exterior use.

Lithopone and allied pigments are sold under many trade names, nearly every maker having a distinctive name for his own product and claiming for it exceptional qualities. Some of the best known trade names in use are Beckton white, Ponolith, Zincolith lithopone, Sterling lithopone, Marbon white, and Fulton white. Some lithopone is still imported under the old name "zinc sulphide white." Various grades of lithopone are recognized in the trade. Green seal is the best and the nearest equivalent of French process zinc oxide; red seal, blue seal, and yellow seal are relatively poorer grades. The poorer grades are produced by mechanically mixing ground barytes or blanc fixe with lithopone, resulting approximately in the following proportions of zinc sulphide and barium sulphate:

	Zinc sulphide.	Barium sulphate.
Green seal	1 part	2 parts.
Red seal	1 part	3 parts.
Blue seal	1 part	4 parts.
Yellow seal	1 part	5 parts.

PRODUCTION AND PRICE.

Lithopone was manufactured and sold by nine companies in the United States in 1918. Although the quantity sold in 1918 was 1,300 tons less than that sold in 1917, it was considerably greater than that sold in 1916 and about 16,000 tons more than was sold in 1915.

This increase was due largely to the great demand for the pigment as a flat wall paint. Of the 62,403 short tons put on the market, about two-thirds came from plants in New Jersey and Pennsylvania. Two plants in Delaware and Maryland also produced considerable lithopone. The quantity marketed from the seven plants in the four adjoining States centering around Philadelphia amounted to nearly 52,000 short tons, a decrease of about 6,000 tons from the output in 1917, the falling off being chiefly in Delaware. Illinois, with two producing plants, also had a large production and marketed 2,500 tons more than it did in 1917. Missouri, the source of most of the ore in the central part of the country, had a relatively small production of lithopone, which was, however, a good start for an industry only two years old in the State.

The average price obtained for all the lithopone made and sold in 1918 was $126.97 a short ton, or 6¾ cents a pound, as compared with $116.25, or 5.8 cents a pound, in 1917. The highest average price for the year received by any one company was $140 a ton. The wholesale prices quoted in New York [1] for lithopone in bags ranged from 6½ to 7 cents a pound in the early part of 1918, rose to 8 to 8½ cents in September, and at the end of November fell again to 7½ to 8½ cents. The prevailing prices in 1917 were somewhat lower, ranging from 6¼ to 7 cents.

The following manufacturers reported production and sale of lithopone, or barite-zinc compounds of similar composition and use, in 1918:

Butterworth-Judson Corporation, 61 Broadway, New York, N. Y.; plant at Newark, N. J.

Chemical Pigments Corporation, 825 Stock Exchange Building, Philadelphia, Pa.; plant at St. Helena, Md.

E. I. Du Pont de Nemours & Co., Wilmington, Del.; plants at Camden and Newark, N. J, and Philadelphia, Pa.

Grasselli Chemical Co., Cleveland, Ohio; plant at Grasselli, N, J.

Krebs Pigment & Chemical Co., Newport, Del.; plant at Newport.

Midland Chemical Co., 80 East Jackson Boulevard, Chicago, Ill.; plant at Argo, Ill.

Mineral Refining & Chemical Corporation, Carondelet Station, St. Louis, Mo.; plant at St. Louis.

New Jersey Zinc Co., 55 Wall Street, New York, N. Y.; plant at Palmerton, Pa.

Sherwin-Williams Co., 601 Canal Road, Cleveland, Ohio; plant at Kensington, Ill.

BARIUM CHEMICALS.

Under barium chemicals are included all manufactured chemical compounds that contain barium, and this classification logically includes lithopone, but as the manufacture of lithopone is an industry by itself entirely independent of the barium-chemical industry, it has been separately treated. Many barium chemicals are secondary compounds made from other barium chemicals and not directly from barytes or other barium minerals. As this report deals with barytes and its immediately derived products, only those chemicals that are made directly from barytes or those that are manufactured in the same plant from primary salts of barium so made will be described here. Chemicals that are made from barium chemicals bought in the open market from other factories will therefore not be described and have not been included in the production tables.

[1] Oil, Paint, and Drug Reporter, vols. 93 and 94. 1918.

METHODS OF MANUFACTURE AND USE.

The methods of manufacture of the barium chemicals here described have been briefly given by J. M. Hill.[1]

Most barium chemicals have a wide variety of use.

Barium binoxide or peroxide (BaO_2) is used largely in the manufacture of hydrogen peroxide, in which blanc fixe is a by-product. It is used also to some extent in the preparation of oxygen, for it has the property of readily giving off oxygen under certain conditions and of taking up oxygen again under other conditions. In a similar capacity it is used as a bleach for straw hats and blankets, Barium monoxide (BaO) is an intermediate compound from which binoxide and hydroxide are made.

Barium carbonate is used chiefly in the brick industry to produce an even color in brick and terra cotta and to prevent a white efflorescence on exposed surfaces. It is being used more and more in steel manufacture in making case-carbonized steel. It is used also in the manufacture of optical glass, flat wall paints, and rat poisons, and to glaze earthenware. It is also a water softener. As a paint component, its hiding quality is considered to be intermediate between lithopone and blanc fixe. When mixed with zinc oxide it is claimed by some to equal a mixture of white lead and zinc oxide. It is a chemical from which many other secondary barium chemicals are made.

Barium chlorate is used in pyrotechnics and to some extent in explosives.

Barium chloride is used largely in the purification of table salt, removing all traces of magnesium and sodium sulphates. It is also a mordant in the precipitation of dyes on inert bases, such as blanc fixe and aluminum hydrate, to form lake pigments. Its uses, however, are many and cover most of those of barium carbonate, including the prevention of efflorescence on bricks. It is a chemical from which many other barium compounds are made, and during the European war it entered into the manufacture of chemicals for war purposes, blanc fixe being a by-product in the process. Barium chloride and calcium chloride are employed in the manufacture of hard lead as a substitute for antimonial lead in some of its many uses, including shrapnel bullets. In this process barium and calcium are alloyed with the lead when in a molten state by electric currents. The resulting alloy is heavier and less brittle than antimonial lead, and one of its chief uses is in making thrust washers in automobile differential gears.

There are many uses to which barium hydroxide can be applied. It is employed in the refining of sugar in France, but because of its poisonous nature it is not generally used for this purpose.

Barium nitrate is used largely in the preparation of green fire or Bengal fire in pyrotechnics, in green signal lights, and in powders to give an artificial driftwood blaze to log fires in open fireplaces. It is also used in the manufacture of tonite, an explosive made of guncotton and barium nitrate, and of saxifragine, made of charcoal and barium nitrate.

Chemically precipitated barium sulphate, sold on the market as blanc fixe, permanent white, or constant white, is a pigment of

[1] Hill, J. M., Barytes and strontium, U. S. Geol. Survey Mineral Resources, 1915, pt. 2, pp. 182–184, 1916.

superior quality. It is finer, more impalpable, and of more even grain than ground water-floated barytes, which has the same chemical composition, but is crystalline instead of amorphous. It therefore has greater opacity than ground barytes, is whiter, and does not settle in the oil vehicle as badly as barytes. Although used to considerable extent in flat white paints, it is largely used as the inert base in the manufacture of organic lake pigments and colored lithographic inks. It is also used in the manufacture of highly glazed white paper, oilcloth, linoleum, rubber goods, and putty. It is largely a by-product of the manufacture of other chemicals.

Barium sulphide when refined is used as a laboratory reagent. It sometimes enters the market in the crude form, called black ash, resulting from calcining barytes with coal in the proportion of 4 to 1, which is the first step in the process of making most other barium compounds. Barium sulphide is mixed with phosphate tailings from iron concentrating plants and finely ground, and the mixture is sold as a fertilizer called "barium phosphate." When used on fields the barium sulphide is said to act on the calcium phosphate in the mixture and set free phosphoric acid.

PRODUCTION.

The manufacture of barium chemicals in the United States, which practically began in 1915 with an output of 8,823 tons, was nearly doubled in 1916 and nearly trebled in 1917. The quantity marketed in 1918 was 23,186 short tons, an increase of 683 tons over that sold in 1917.

Barium chemicals were made either directly or indirectly from crude barytes in 1918 in 11 plants in the United States, two of which are on the Pacific coast (in California), three on the Atlantic seaboard (in New York and New Jersey), and the rest in Illinois, Ohio, Tennessee, and West Virginia.

The Durex Chemical Co., of New York, with plants at Long Island City, N. Y., and Sweetwater, Tenn., manufactured and sold five of the seven chemicals here enumerated and leads in total output. The Rollin Chemical Co., of Charleston, W. Va., which stands next in the quantity produced, made six of the seven products. The Clinchfield Products Corporation, of New York, with plant at Johnson City, Tenn., was the only other large producer of barium chemicals.

Barium chemicals of domestic manufacture sold, 1915–1918.

Chemical.	1915	1916	1917	1918
	Quantity (short tons).	Quantity (short tons).	Quantity (short tons).	Quantity (short tons).
Barium binoxide	(a)	1,980	(a)	(a)
Barium carbonate	2,746	6,844	8,238	7,661
Barium chloride	2,106	3,643	4,870	4,530
Barium nitrate	971	446	165	(a)
Barium sulphate (blanc fixe)	(a)	3,337	6,314	9,522
Other barium chemicals b	3,000	542	2,916	1,473
	8,823	16,792	22,503	23,186

a Included under "Other barium chemicals."
b Includes, 1915: Binoxide, hydroxide, sulphate, sulphide, and other barium chemicals not specified; 1916: Hydroxide and sulphide; 1917: Binoxide, hydroxide, and sulphide; 1918: Binoxide, hydroxide, nitrate, and sulphide.

Barium binoxide manufactured from barytes was marketed by only two firms in 1918. One other plant reported the manufacture of binoxide from barium salts purchased in the open market, and its product is not included in the preceding table of statistics. The quantity reported as sold, including the product of the latter plant, was less than 1,250 short tons. The average price obtained was $418 a ton.

Barium carbonate was manufactured and sold by five firms in the United States, which put on the market 7,661 tons, as compared with 8,238 tons in 1917. About 88 per cent of this output was produced by three firms in the eastern part of the country. The average price obtained was $48.18 a ton.

Barium chloride was marketed by eight firms in 1918, two of which are in California, two in Illinois, and the rest in the eastern part of the country, and which produced 4,530 tons, as compared with 4,870 tons in 1917. The average price received was $71.62 a ton.

Barium hydroxide was manufactured by only one firm using crude ore in the United States in 1918, and the quantity sold was very small. Likewise only small quantities of barium nitrate and barium sulphide were made in two plants using crude ore.

Barium sulphate or blanc fixe was manufactured and sold in 1918, by five firms, all in the eastern part of the United States. The quantity marketed by them, 9,522 tons, showed an increase of more than 50 per cent over that of 1917, which was 6,314 tons. Most of this was produced in plants in New York, Tennessee, and West Virginia, partly as a by-product in the manufacture of other chemicals. The average price obtained was $44.78 a ton.

In comparison with the prices given above received at the plants for barium chemicals, the following table gives the range in wholesale market price in New York during 1918:

Monthly range of wholesale market prices in New York for barium chemicals, 1918.[a]

Month.	Blanc fixe (barium sulphate) dry in barrels.	Barium chlorate.	Barium chloride.		Barium dioxide.	Barium nitrate.

[a] Oil, Paint, and Drug Reporter, vols. 93 and 94, 1918. [b] Nominal.

The increase in price of blanc fixe from 3¾ to 4 cents a pound, approximately the price that prevailed during 1917, to 5½ to 6 cents in June 1918 was apparently due to increased demand for the product, and this may have been in part the cause of the large increase of production of this compound during the year. Barium nitrate,

on the other hand, declined from the price of 15 to 16 cents a pound early in 1917 to between 11 and 14 cents, which prevailed during the whole of 1918. This decline in price and the corresponding decline in output were probably due to decreased demand for the material for war purposes.

The following domestic manufacturers reported that they had made barium chemicals directly or indirectly from crude barytes during 1918:

American Barium Co., 57 Post Street, San Francisco, Calif.; plant at South San Francisco.

Ault & Wiborg Co., Cincinnati, Ohio; plant at St. Barnard, Ohio.

Barbour Chemical Works, 707 American National Bank Building, San Francisco, Calif.; plant at Melrose, Calif.

Chicago Copper & Chemical Co., 111 West Jackson Boulevard, Chicago, Ill.; plant at Blue Island, Ill.

Clinchfield Products Corporation, 120 Broadway, New York, N. Y.; plant at Johnson City, Tenn.

Durex Chemical Co., 320 Fifth Avenue, New York, N. Y.; plants at Long Island City, N. Y., and Sweetwater, Tenn.

Grasselli Chemical Co., Cleveland, Ohio; plant at Grasselli, N. J.

Midland Chemical Co., 80 East Jackson Boulevard, Chicago, Ill.; plant at Argo, Ill.

Oakland Chemical Co., 10 Astor Place, New York, N. Y.; plant at New York.

Rollin Chemical Co., Charleston, W. Va.; plant at Charleston.

IMPORTS.

The value of imports of barium products, including ground witherite or natural barium carbonate, declined from $459,841 in 1916 to $59,669 in 1917, and shrank still further to only $15,127 in 1918. This reduction was due to the fact that there were no ground barytes nor barium chemicals imported in 1918 and only a little lithopone imported under the name "zinc sulphide white," so that the usual quantity of ground and refined natural barium carbonate, or witherite, which is duty free, formed the bulk of the imports of barium products. Although the value of the barium carbonate imported in 1918 was approximately the same as the average for the preceding five years, it was somewhat less than the value of the imports in 1917 and in 1916. Since the term "lithopone" was introduced in 1913 it has found general use and has almost supplanted the older term "zinc sulphide white."

Value of barium products imported and entered for consumption in the United States, 1912–1918.[a]

PETROLEUM.

By E. Russell Lloyd.

INTRODUCTION.

GENERAL CONDITIONS.

The year 1918 was one of exceptional interest in the petroleum industry as well as in all other great industries. It witnessed the organization of the industry on a war basis under the direction of the United States Fuel Administration, a quickening of activity in all phases of the industry, and an active coordination of all its branches in a complete and unified organization for the one purpose of supplying petroleum products for the necessary operations of the United States and the Allied nations in winning the war. This organization was accomplished largely by the industry itself through the National Petroleum War Service Committee working in close harmony with the oil division of the United States Fuel Administration. The result was obtained with a minimum of Government control, and the soundness of the principles upon which the organization was based was proved not only by the successful accomplishment of the immediate objective but also by the fact that the transition from a war to a peace basis required a minimum of adjustment.

On January 10, 1918, M. L. Requa was appointed director of the oil division of the United States Fuel Administration and immediately took active steps to organize his division. Mr. Requa promptly relieved the uncertainty in the minds of many oil operators and distributors, who feared that the industry might be taken over as a whole by the Government, by the timely announcement that the industry would be called upon to cooperate with the Government in every way possible, but that Government control and Government supervision would be kept at a minimum. Organization of the petroleum industry was effected through the National Petroleum War Service Committee, of which A. C. Bedford was chairman. A proclamation by President Wilson, effective on January 11, 1918, placed the manufacturing and distribution of fuel oil under Government control by means of a leasing system. This control extended to all firms marketing more than 100,000 barrels of fuel oil a year.

Mr. Requa found that one of the greatest problems before the oil division of the Fuel Administration was to secure adequate transportation, and as a result of the intensive demand for petroleum products an order was issued from the office of the Director General of Railroads, effective on January 31, exempting petroleum and petroleum products from embargoes on all railroads in the country.

Early in the year the price of the Pennsylvania grade of crude oil rose from $3.75 to $4 a barrel and prices of other grades of oil throughout the country were advanced in corresponding ratio. When further advances in the prices of crude were threatened Mr. Requa wrote to Chairman Bedford of the National Petroleum War Service Committee

that in his opinion there was no justification for an advance in the price of crude oil at that time and that the oil division would expect full cooperation from the producers in an endeavor to maintain the existing prices for crude oil as maximum prices. The Petroleum War Service Committee reported a proposed method for stabilizing the prices of crude and for establishing definite and fixed differentials for various grades of crude. This plan was submitted on August 6, 1918, and its adoption was largely responsible for the maintenance of prices of crude oil at a constant level during the remainder of the year.

In 1918 interest was centered primarily on the problem of increasing the production to meet the enormously increased requirements for petroleum products. The results were highly creditable and showed marked increase in production despite increasing difficulties—difficulties not only of an abnormal nature caused largely by war conditions but also the inherent difficulties of finding new pools and of overcoming the increase in average depth to which it has become necessary to drill. The resultant increase in production, although not so great as in 1917, was comparable to the increase in other recent years but failed by a wide margin to keep pace with the demands. Since 1915 the quantity of domestic petroleum consumed in and exported from the United States has exceeded the domestic production by an increasing quantity.

Much of the deficit in our domestic supply in 1918 was made good from the prolific Mexican fields. Here again difficulties of the gravest nature threatened the supply. The unsettled condition of the country and the hostile attitude of the Mexican Government rendered extremely hazardous both the lives and the property of American citizens operating in that country. Despite the drawbacks, the Mexican industry stood ready to furnish an abundant supply of petroleum, but serious impediments resulted from a lack of tanker facilities incident to the prime necessity of diverting a considerable proportion of the tanker fleet to the purpose of carrying war supplies to Europe.

The industry was confronted by numerous difficulties during the year. Weather conditions in the earlier months were exceptionally severe, resulting in a marked curtailment of production; insufficient transportation facilities proved a very serious handicap; shortage of supplies manifested itself particularly in its effect on production; and the drilling of new wells was hindered by lack of drilling rigs and casing. This scarcity of material also delayed the extension of pipe lines to the newer fields of northern Texas. The lack of skilled labor became a menace toward the end of the summer, and the epidemic of influenza seriously hampered the industry in the fall. Despite these obstructions the industry made rapid strides forward, not only in the opening of new fields but particularly in the intensive development of pools already discovered.

SIGNIFICANT DEVELOPMENTS.

The one region of outstanding interest in 1918 was northern central Texas, in which development was focused in two districts—the deep sand areas of Eastland, Stephens, and northern Comanche counties, and the comparatively shallow prolific pool at Burkburnett, in Wichita County. The campaign of wildcat drilling radiating from

these centers extended over a large part of western Texas before the end of 1918. Second in importance to the northern Texas development only was the intensive development of the Pine Island pool in Caddo Parish, northern Louisiana, the development of a number of prolific shallow pools in Kentucky, and the development of the prolific Montebello and Casmalia pools in California and the Big Muddy pool in Wyoming. Important discoveries of new pools included the Youngstown pool, Okmulgee County, Okla.; new territory in Stephens County, Okla.; important extensions of the deep sand areas of northern Texas; the Burkburnett shallow pool, Wichita County, Tex.; new and prolific domes at West Columbia in Brazoria County and at Hull in Liberty County, Tex.; the Homer field in Claiborne Parish, La.; the important Lance Creek pool in Niobrara County, Wyo.; and a very significant find in the Elk Hills district in San Joaquin Valley, Calif.

ACKNOWLEDGMENTS.

This report is designed as a record primarily of the producing branch of the domestic petroleum industry, but includes also figures concerning the consumption of crude oil and some data on the production of petroleum in foreign countries. The present chapter is the thirty-seventh in the series of statistical records of the petroleum industry issued by the United States Geological Survey since its organization and follows very closely the form of previous chapters. The statistical tables have been prepared by Misses A. B. Coons and M. N. Schellenger, of the United States Geological Survey, with the exception of those relating to imports and exports, which were compiled from the records of the Bureau of Foreign and Domestic Commerce, Department of Commerce, by J. A. Dorsey, also of the Geological Survey. The writer is indebted to Mr. Walter A. English for the description of developments in California in 1918. Valuable suggestions have been received from Mr. Frank W. De Wolfe, State geologist of Illinois, and from Prof. J. A. Bownocker, State geologist of Ohio, concerning operations in those States.

The tables on production are compiled from data furnished by producing, transporting, and refining companies throughout the United States. It is only through the continued and active cooperation of those engaged in the industry that these reports are possible.

PRODUCTION.

GENERAL STATEMENT.

The term "production" as used in this report has the same meaning as "marketed production" in the petroleum statistical reports for 1914, 1915, and 1916, and as "petroleum marketed" in the report for 1917, published as chapters of the volumes on Mineral Resources of the United States. The term "marketed production" has caused misunderstanding and has been interpreted to mean deliveries to refineries and to other consumers. The quantity of crude petroleum produced in the United States in 1918, as shown by runs to pipe lines from field sources and by shipments from wells by tank cars or wagons, including oil used for field development, aggregated 355,927,716 barrels of 42 gallons each. This established a new record

for output of petroleum in this country that is more than 6 per cent greater than the former maximum yield of 335,315,601 barrels, attained in 1917.

The average price received for this oil at the wells was $1.978 a barrel, and the total market value of the output was $703,943,961, a gain of 42 cents in average unit price and of $181,308,748, or 35 per cent, in gross market value, compared with 1917.

The figures of production given above are in excess of the actual amount of petroleum taken from the ground during 1918 by the net decrease during the year of stocks of crude oil held by producers and not delivered to marketing companies. According to the best available data, this net decrease amounted to 6,158,714 barrels. Deduction of this quantity from the figures of production given above indicates that approximately 349,769,000 barrels of petroleum was taken from the ground in 1918.

STATISTICS.

Petroleum produced in the United States in 1917 and 1918, by months, in barrels of 42 gallons.

[a]Alaska and Michigan.

RANK OF PRODUCING STATES.

Changes in rank of producing States based on the quantity produced were not important in 1918 as compared with 1917. The position of the first four States, Oklahoma, California, Kansas, and

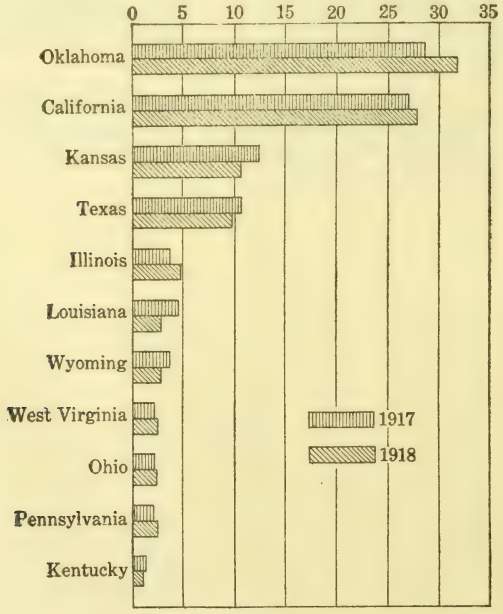

FIGURE 100.—Percentage of total quantity of petroleum produced in the United States in 1917 and 1918, by States.

Texas, remained unchanged; Louisiana advanced from sixth to fifth place, displacing Illinois; Pennsylvania advanced from tenth to ninth place, displacing Ohio; and Indiana advanced from thirteenth to twelfth place, displacing New York.

Changes in rank based on the value of the production were similarly unimportant.

CLASSIFICATION BY FIELDS.

GENERAL STATEMENT.

For convenience of discussion the oil pools of the United States are grouped in certain major areas or fields based originally on geographic position alone. As these fields have been extended areally, the geographic boundaries have become less distinct, and the separation has come to indicate more and more fundamental differences in the type of oil produced and its adaptability to refining needs. Thus the oils of the Appalachian field are in the main of paraffin base, free from asphalt and objectionable sulphur, and they yield by ordinary refining methods high percentages of gasoline and illuminating oils—the products in greatest demand. Contrasted with these oils is the petroleum of the Lima-Indiana field, which contains some asphalt, though consisting chiefly of paraffin hydrocarbons, and is contaminated with sulphur compounds which necessitate special treatment for their elimination.

Illinois oils contain varying proportions of both asphalt and paraffin and differ considerably as to specific gravity and products of distillation. Sulphur is generally present, but rarely in such form as to necessitate special treatment for its removal.

Mid-Continent oils vary in composition within wide limits, ranging from asphaltic oils, poor in gasoline and illuminants, to oils in which the asphalt content is negligible and the paraffin content relatively high and which yield correspondingly high percentages of the lighter products on distillation. Sulphur is present in varying quantities in the lower-grade oils, in certain of which—Healdton grade, for example—it exists in the form requiring special treatment for its elimination.

Oils from the Gulf field are characterized by relatively high percentages of asphalt and low percentages of the lighter products of distillation. Considerable sulphur is present, much of which, however, is in the form of sulphureted hydrogen and is easily removed by steam before refining or utilizing the oil as fuel.

Oils from Wyoming and Colorado are in the main of paraffin base, suitable for refining by ordinary methods. Heavy asphaltic oils of fuel grade are also obtained in certain of the Wyoming fields. The California oils are generally characterized by much asphalt and little or no paraffin and by varying proportions of sulphur. The chief products are fuel oils, lamp oils, lubricants, and oil asphalt, though low percentages of naphthas may be derived from certain of the lighter oils, notably those of the Santa Maria, Sespe, and Santa Paula fields, in the southern part of the State.

PETROLEUM PRODUCED.

The following table shows the annual distribution, by fields, of the petroleum produced in the United States since 1859 and the total quantity contributed by each field since the beginning of the petroleum industry in this country:

137536°—M R 1918—PT 2——62

Petroleum produced in the United States, 1859–1918, by fields, in barrels of 42 gallons.

[a] Includes 40,180 barrels of lubricating oil.
[b] Includes 27,823 barrels of lubricating oil.
[c] Includes small quantity used for hog dip.
[d] Includes 366 barrels used for hog dip and street sprinkling.

STOCKS AND STORAGE.

By far the larger quantity of unused crude petroleum above ground in the United States is held in large storage farms by the pipe-line and marketing companies. Oil thus held is described as "pipe-line stocks" or "stocks." A smaller quantity of crude oil is also held in storage at refineries, in most places only a quantity necessary for immediate use. Such oil is described as "refinery stocks." In general the producing companies do not hold oil in storage except as they are forced to do so by lack of marketing facilities. In newly developed territory, however, the quantity of crude oil held in storage by the producers themselves sometimes reaches considerable magnitude. Oil run into such temporary storage is included in field stocks. Another type of stored oil which has hitherto been included in field stocks is oil held in storage by certain marketing companies which are not, however, pipe-line companies. Such stocks are in this report included in pipe-line stocks, although in previous years they have been included in field stocks.

PIPE-LINE STOCKS.

The statistics tabulated below show the quantities of crude oil of various grades in the custody of the pipe-line companies of the United States at the close of business on December 31, and include also the stocks held at storage centers by important purchasing and marketing agencies other than pipe-line companies.

Stocks of all grades of petroleum at the end of 1917 and 1918, in barrels.

Grade of oil.	Held by eastern pipe lines and refineries.[a]		In pipe-line storage outside of eastern field.		Total.		Increase or decrease.

[a] These pipe lines connect with the delivering lines of the Illinois, Kansas, and Oklahoma fields and receive and transfer large quantities of these western oils to the Atlantic seaboard in addition to the oil from wells directly tributary to their own systems.

[b] Includes natural lubricating oil from Pennsylvania and West Virginia.

[c] Includes some Indiana oil of Illinois grade.

REFINERY STOCKS.

Statistics compiled and published by the Bureau of Mines show that the quantity of crude oil on hand at the petroleum refineries of the United States at the close of business on December 31, 1918, was not less than 15,700,000 barrels. A small part of this working stock is certainly duplicated in the foregoing tabulation of pipe-line stocks, owing to the fact that many refining companies which receive all or a part of their supply of crude oil through private pipe lines make no distinction in their records between pipe-line and refinery stocks of crude oil.

FIELD STORAGE.

The following table shows the quantity of unmarketed petroleum reported by the producers as held in field tanks and reservoirs at the close of business on December 31, 1917 and 1918:

Petroleum in field storage at end of 1917 and 1918.

a Including gas wells.

PETROLEUM OPERATORS' STATISTICS.

The statistics presented in this section are those obtained directly from the oil producers The object of this investigation, in addition to providing a check on the determination of petroleum produced, as reported by the pipe-line and other oil-transporting companies, is to procure a record of petroleum utilized in field operations and to obtain details available in no other way concerning field storage, drilling activity, and acreage held for development.

It will be noted that the statistics of wells completed as given in this section differ with respect to many States and districts from those given elsewhere in this chapter. The statistics presented here are those obtained from voluntary reports by the petroleum operators themselves and relate merely to the number of wells owned or operated by the particular companies reporting. Those published elsewhere, with the exception of the field reports for Colorado, Wyoming, Montana, California, Missouri, Alaska, and miscellaneous, which are obtained from the statements of the operators, are compiled from trade journals, principally the Oil City Derrick and the Oil and Gas Journal, and are published because they are consistent since the beginning of the oil industry in the United States and because they furnish, in addition to the number of wells completed, an approximation of the output of each well the first day of its productive life.

Well record and acreage held by operators in the United States in 1918.

PIPE-LINE STATISTICS.

With the statistics furnished by pipe-line and other transporting agencies are incorporated, wherever appropriate and without differentiation, the statistics of fuel consumed in field operations and the statistics of local sales of crude petroleum by producers, concerning which the transportation companies have no record.

APPALACHIAN OIL FIELD.

GENERAL STATEMENT.

The Appalachian field embraces all oil pools east of northwestern Ohio and north of central Alabama, including those of New York, Pennsylvania, West Virginia, southeastern and central Ohio, Kentucky, Tennessee, and northern Alabama. Its total length is about 500 miles and its broadest part centering in eastern Ohio is about 150 miles. The area of greatest oil development occupies a narrower zone which averages less than 50 miles in width and centers in the panhandle of West Virginia.

"The oil and gas bearing sands occur throughout a long stratigraphic interval, including rocks ranging in age from Ordovician to Carboniferous. The strata consist of preponderating shale, lenses of sandstone—which are the main oil and gas reservoirs—and subordinate limestone. The sandstones merge into shales toward the west, where there is also a greater proportion of limestone in the section. There is a marked decrease in thickness of the strata toward the west, notably of the Upper Devonian. This is shown by the increase in the interval between the Berea sandstone and the Corniferous limestone, from 500 feet in central Ohio to more than 5,800 feet in northern West Virginia. To the south across West Virginia there is a notable thickening of the Pottsville formation. For this reason and because of the basin structure of the district the 'Clinton' sandstone, which occurs between 2,000 and 3,000 feet beneath the surface in central Ohio, is more than 7,000 feet deep in western Pennsylvania and

northern West Virginia, where it was not encountered in two recently sunk very deep test holes.

"The Appalachian oil and gas district lies in the geosyncline that extends between the Cincinnati anticline on the west and the zone of steeply folded rocks of the Allegheny Mountains on the east. The syncline is a spoon-shaped trough in which the rocks rise northwestward, northward, and southeastward from the lowest part of the basin, in West Virginia near the southwest corner of Pennsylvania. Superimposed on this larger structural feature are a series of folds by which the rocks are warped into irregular and generally nonpersistent anticlines and synclines, whose axes undulate and overlap. The axial trend throughout the greater part of the district is northeast, but in southern West Virginia and Kentucky the trend becomes more westward. The folds decrease in intensity westward from the eastern margin of the district, and west of the axis of the geosyncline the folding is so gentle that the rocks are warped into irregular wrinkles without marked axial trend. Along the western margin of the district the folds practically disappear and give way to a monocline on which the rocks rise westward at the rate of about 60 feet to the mile.

"In the region considered as a whole the most productive oil belt is contiguous to the central axis of the geosyncline and the largest accumulations of gas are found along the outer margins of the trough. But pools of oil and gas of varying size separated by nonproductive areas are irregularly distributed throughout the district. The pools are characteristically elongated in outline, and their longer dimensions are prevailingly parallel to the structural trend. The location of most of the gas pools has been distinctly determined by structure. They occur along the crests of anticlines or along the up-dip termination of lenses of sandstone where they merge with shale or where there is a marked decrease in porosity of the pay sand. The influence of structure on oil accumulation is also pronounced. In the absence of gas, some oil pools occur on the crests of anticlines. Where much gas is present the oil pools occur on the flanks of anticlines below the gas and above the edge water; others occur on terraces marked by changes in the rate of dip. In the absence of water in the rocks petroleum tends to occur in the synclines. In many pools, however, the effect of structure is not so evident and lithology has been the controlling factor. The location of many of the oil pools in the Appalachian region is due principally to the position and porosity of the lenticular reservoir rocks. These factors account for the irregular shape of many of the pools and for their not uncommon occurrence 'off structure.'

"The petroleum from the Appalachian region is a high-grade paraffin oil. The product of New York, Ohio, Pennsylvania, and West Virginia has an average specific gravity not far from 0.800 (45° Baumé). The average for Kentucky is not quite so high.

"Extension of the production curve indicates that approximately 85 per cent of the recoverable oil from New York and Pennsylvania has been exhausted under present operating conditions.

"Wells in the Appalachian region are sunk by the standard or churn system of drilling. The rocks are hard and comparatively little casing is required, as contrasted with drilling in the loosely consolidated rocks of other districts. The wells range in depth from a few hundred feet in parts of eastern Ohio and Kentucky to between

3,000 and 4,000 feet to reach the deeper sands in southern Pennsylvania and West Virginia." [1]

The total output of crude petroleum from the Appalachian field in 1918 was 25,401,466 barrels, a quantity greater by 469,261 barrels, or more than 1 per cent, than the output in 1917. The principal increase in production was in the newer fields of Kentucky. Southeastern Ohio showed a slight increase, but New York, Pennsylvania, and West Virginia showed a normal decline of about 5 per cent.

The average price received at the wells for all grades of Appalachian oil was $3.697 a barrel, a gain of $0.577, or 18 per cent, over the average in 1917. The market value of the oil sold was approximately $93,917,171, a gain of $16,130,676, or about 21 per cent, as compared with the market value of the output in 1917. The quoted market price for Pennsylvania grade of petroleum, which includes the greater part of the oil produced in the Appalachian field, rose on February 8 from $3.75 to $4 a barrel, and maintained this level throughout the year. Other grades showed a corresponding increase.

Activity in drilling was somewhat less in 1918 than in 1917 in the Appalachian field as a whole. In all, 7,203 wells were completed in 1918, a decrease of 467, or 6.1 per cent, from the previous year's record. Of the wells drilled in 1918, 4,872, or 67.6 per cent, were oil wells credited with an average yield of 16.4 barrels each the first day of productive life, 1,068 were gas wells, and 1,263, or 17.5 per cent, were dry holes.

The following tables include essential statistics of the petroleum industry in the Appalachian oil field in 1918 and in other recent years:

PETROLEUM PRODUCED.

[a] These pipe lines connect with the delivering lines of the Illinois, Kansas, and Oklahoma fields and receive and transfer large quantities of these western oils to the Atlantic seaboard in addition to the oil from the wells directly tributary to their own systems.

[b] Includes natural lubricating oil from Pennsylvania and West Virginia.

PRICES OF APPALACHIAN OIL.

Prices paid at wells by the Seep Purchasing Agency for petroleum produced in the Appalachian field in 1917 and 1918.

PENNSYLVANIA.

GENERAL STATEMENT.

The output of petroleum in 1918 credited to Pennsylvania was 7,407,812 barrels, a decrease of 325,388 barrels, or 4 per cent, compared with the output in 1917. The records for Pennsylvania show a retrograde movement in practically all phases of the industry except value—a decrease in production, in number of wells drilled, and a very marked decrease in the average initial production of new wells. The decline in the percentage of dry holes, as compared with 1917, and in the number of wells of 100 barrels or more of initial capacity shows a marked decline in efforts to discover new territory. The average price received at the wells for all grades of oil produced in Pennsylvania in 1918 was $3.997 a barrel and the total market value of the oil produced was $29,606,079, a gain of 74.4 cents in average unit price and of $4,451,789 in gross market value, as compared with 1917. The posted price for Pennsylvania grade oil rose on February 8 from $3.75 to $4 a barrel, but it was undoubtedly the influence of the oil division of the Fuel Administration which prevented further rise in price.

DEVELOPMENT.

Inclusive of the New York portion of the Bradford district, 1,837 new wells were drilled for oil in Pennsylvania in 1918, a loss of 539 wells, or 23 per cent, as compared with 1917. Of these, 1,423, or 77 per cent, were completed as oil wells and credited with an average yield of 3 barrels each during the first day of productive life, 202 were gas wells, and 212, an average of 1 in every 9 drilled, were failures.

No new pools of importance were discovered in Pennsylvania during the year 1918, development work being confined largely to intensive development of proved territory.

The old Bradford district alone of the Pennsylvania fields showed an increase in number of new wells drilled. There was, however, a decrease in initial production of new wells and an increase in the percentage of dry holes.

The investigations of the Internal Revenue Bureau show that a fair average production for the Bradford district is a quarter of a barrel per well per day but that the wells have an exceptionally long life. The recent introduction of the so-called water drive, which consists of the flooding of certain wells with water in order to increase the production of near-by wells is reported to have met with great success.

It is noteworthy that only 2 to 3 per cent of the wells drilled in this district in recent years are dry holes.

The middle district, embracing the areas of oil production in Warren, Elk, and Forest counties and the Venango-Clarion-Jefferson district both show an increase in the average initial production of new wells but a marked decrease in total number of wells completed. In 1918, 11.5 per cent of the wells drilled in the middle district and 9.5 per cent of the wells in the Venango-Clarion district were dry holes, results not markedly different from the results of efforts in other recent years.

In Butler and Armstrong counties less than half as many new wells were drilled in 1918 as in 1917. There was also a considerable reduction in average initial output. The only favorable feature was a considerable decrease in the percentage of dry holes—19.7 per cent in 1918, as compared with 23.6 per cent in 1917.

In the southwestern district results were still more discouraging. The average initial production of new wells drilled was only 7.6 barrels, as compared with 20 barrels in 1917. A marked decrease in the number of wells drilled with a considerable decrease in the proportion of dry holes shows the general falling off in efforts to find new productive territory.

Field work in the Pennsylvania and New York districts was more unsatisfactory during 1918 than for a decade. Material was scarce, prices high, and experienced drillers and tool dressers were scarce. The work throughout the year was of the most routine character. Very few wells of important size were obtained and the work was practically confined to old leases. One unexpectedly rich spot was found at Pioneer on Oil Creek, which was originally drilled in the sixties. Several good wells in Clarion County were brought in by the Peoples Natural Gas Co. on the Dwyer Farm, in Red Bank Township, and by other companies on adjacent farms. A revival of interest in Warren County was occasioned by the bringing in of good wells by the Interior Oil & Gas Co. near Deerlick field, northwest of Sheffield.

Only 15 wells having an initial output of 100 barrels or more are reported in Pennsylvania in 1918. Of these 9 were in Greene County, 4 in Allegheny County, and 2 in Clarion County. The largest well reported was No. 4 of the Manufacturers Heat & Light Co., on the Strope tract in Greene County, which started with an initial production at the rate of 280 barrels per day.

NEW YORK.

The production of petroleum from the old pools in New York showed a normal decrease of 8 per cent, which is correlative with a 6 per cent decrease in the number of wells drilled in the Allegany district. Work in these old pools was of a routine nature and resulted in the drilling of 171 wells in the Allegany district, of which 154 were oil wells with an average initial daily production of 1.8 barrels, 10 were gas wells, and 7, or more than 1 in 25, were failures. The percentage of dry holes was larger and the average initial production less than in other recent years.

WEST VIRGINIA.

GENERAL STATEMENT.

The quantity of petroleum produced in West Virginia in 1918 was 7,866,628 barrels, a decrease of 512,657, or 6.12 per cent, as compared with 1917. This loss, like that in other recent years, is attributed to a rather marked decline in drilling activity, a general failure of wildcat operations to discover new fields of consequence, and to the normal decrease in production of the older pools.

DEVELOPMENT.

The field work done in West Virginia in 1918 included drilling in 18 counties and resulted in the completion of 1,310 new wells, 325 less than in 1917. Of the wells completed, 741 were oil wells with an initial daily output of 19.9 barrels, 329 produced only gas, and 240 were dry holes. The totals for the State show a marked increase in average initial production and an increase from 16.3 to 18.3 per cent in the percentage of dry holes to total number of wells drilled.

Marion County, as in other recent years, led in the number of new wells drilled but Kanawha County made by far the best showing with 102 oil wells having an average initial daily production of 84 barrels, the best record for any county in West Virginia since 1912. More than half of the new production in the State came from this county.

Boone County was added to the list of oil-producing counties in 1918 with 6 new wells drilled, 5 of which were oil wells with an average initial daily production of 14.6 barrels.

The scarcity and high cost of material and labor almost stopped wildcat operations in West Virginia during the year. The one pool that attracted any considerable attention was discovered at Kellys Creek, Cabin Creek district, Kanawha County, where the Columbia Carbon Co. deepened a gas well to the Weir sand to obtain if possible an increase in gas pressure and obtained an oil well with initial flow reported at more than 400 barrels for the first day of productive life. This discovery started an intense town-lot development, and it was estimated that at one time the production from the pool was very nearly 3,000 barrels a day. The decline, however, was rapid, the producing wells being confined to a very small acreage. The grade of crude at Kellys Creek, like that of Cabin Creek, is very high and commands a premium over the regular market price of Pennsylvania grade.

On Little Creek, in Wetzel County, a well drilled in the early spring started producing about 70 barrels a day and was regarded as the forerunner of a new pool. Further drilling, however, resulted chiefly in dry holes.

On the Ella Kinsey farm in Mannington district, Marion County, the Hope Natural Gas Co. obtained a good well in the Gordon sand, which, it was hoped, would open up an extension of the Dents Run pool, but further drilling in this vicinity resulted in more dry holes than producers.

Important deep tests in West Virginia have been drilled by the Hope Natural Gas Co. In May it was reported that the deep test in the old Volcano pool near Volcano, Wood County, found a show of oil at 4,445 feet in sand said by Dr. I. C. White to be the Oriskany. The oil was black and heavy and resembled lubricating oil.

The end of October marked the abandonment by this company of the deep test on the M. O. Goff farm in Simpson district, near Clarksburg, Harrison County. This well was drilled on the Chestnut Ridge anticline and reached the extreme depth of 7,386 feet and when finally abandoned was the deepest well in the world. Another deep test was being drilled at the end of the year by the same company on the J. H. Lake farm, near Fairmont, Marion County.

SUMMARY OF WELLS DRILLED.

The statistics of field operations presented in the following tables are compiled from trade-journal sources and differ somewhat from those on page 985, which are obtained from reports received directly from the oil producers.

KENTUCKY.

GENERAL STATEMENT.

Kentucky was the center of interest in the eastern fields in 1918, and the results are shown in an increase of 41 per cent in production, of 32 per cent in total number of new wells drilled, of 50 per cent in the number of oil wells completed, and of 60 per cent in the value of output. The year was marked by intensive drilling of pools opened up in the previous years and in the active search for new pools and extensions of the older pools. A total of 2,167 wells was drilled during the year, an increase of 529, compared with 1917. Of these 1,737,or 80.2 per cent, were oil wells credited with an average production of 28 barrels for the first day of productive life, 78 were gas wells, and 352 were dry holes.

Increase in drilling costs and scarcity of labor and of all kinds of material tended to discourage the exploration for new territory, whereas increased prices for crude petroleum encouraged the drilling of new wells, especially in proved areas, and the maximum production of oil from producing wells. The results are shown in a marked decrease in the percentage of dry holes and a slight decrease in the average initial production from new wells.

DEVELOPMENT.

Wells were completed in 40 counties in 1918 and productive oil wells were completed in 31 counties. By far the greatest activity was in Lee County, in the eastern part of the State, where a total of 697 wells was completed, of which 656 were oil wells with an average initial capacity of 47.9 barrels. In 1917, only 58 wells were drilled in this county, of which 43 were oil wells with an average initial production of only 18 barrels. This new drilling marks the development of the Big Sinking pool and other smaller pools. The producing area north and east of Beattyville is a southern extension of the Big Sinking pool. Drilling in this section is a little deeper and the wells a little smaller than in the Big Sinking pool. The larger wells in Big Sinking pool in 1918 did not have an initial production of more than 300 barrels a day each.

Next to Lee County in importance as a producing county was Allen County, in the western central part of the State. Operations in this county did not begin on a large scale until 1918, when 219 wells were drilled, of which 174 were rated as oil wells, whose initial production ranged from 10 to 200 barrels a day each. Allen County is essentially a region of shallow wells relatively easy and cheap to operate. The declining production of individual wells, however, is rapid. An increase in drilling activity compared with 1917 was shown in the following counties: Allen, Barren, Estill, Floyd, Lee, Lincoln, Magoffin, Morgan, Ohio, Pulaski, Simpson, Warren, and Wolfe. The following were added to the list of producing counties: Breathitt, Elliott, Hopkins, Johnson, Knott, Menifee, Owsley, and Union.

The new production in Kentucky was taken care of by the Cumberland Pipe Line, which made extensions to the new pools in Estill, Lee, Powell, and Wolfe counties. In addition the National Refining Co. furnished a line from the Big Sinking field in Lee County to Beattyville to handle its production from the Flathaven tract. Two or three

other companies have also put in short lines to handle their own production.

In the western division of the State the most active county was Allen, of which Scottsville is the center. During the year the Indian Refining Co. installed a line from the famous Johnson pool in the north end of Allen County to a loading station at Scottsville, and after finishing that line extended other field lines to take in some of the additional production scattered over Allen County. A few of the producing companies have also installed lines and are shipping crude to outside refineries. Another line that was put in during 1918 was that of the American Pipeline Co., which runs from the Johnson pool through Warren County to its terminus at Bowling Green. Another line is that of the Daniel Boone Oil Co., which was built into Lincoln County and from the field in that county to Waynesburg, where the oil is loaded on tank cars and shipped by train to a refinery at Louisville.

PETROLEUM PRODUCED.

Petroleum produced in Kentucky, 1914–1918, in barrels.

TENNESSEE.

GENERAL STATEMENT.

In 1918 Tennessee was credited with a production of 8,374 barrels of petroleum. This marks a decrease of 3,822 barrels from the production in 1917 but an increase of 7,697 barrels over the production in 1916. During the year 1918, 23 wells are reported to have been completed, of which 14 were oil wells, 3 were gas wells, and 6 were dry holes. Ten of the 14 oil wells were drilled in Scott County, the average reported initial daily yield of which was 24 barrels. The remaining 4 oil wells were sunk in Pickett County.

OHIO.[1]

GENERAL STATEMENT.

Ohio as a whole failed to respond to the increased demand for petroleum in 1918. The decrease took place, however, in the old Lima field in the northwestern part of the State, the central and southeastern parts showing a slight increase. The production of the entire State in 1918 was 7,285,005 barrels, a decrease of 465,535 barrels, or 6 per cent, compared with 1917. The southeastern and central division belonging to the Appalachian field contributed 4,941,841 barrels, or 67.8 per cent, in 1918, as compared with 4,839,679 barrels in 1917. The total value of the oil produced in this territory in 1918 was $18,042,394, an increase of $2,569,689 over the value in 1917, and the average price was $3.65 per barrel, as compared with $3.20 in 1917. The northwestern division, comprising the old Lima field—a part of the Lima-Indiana field—contributed 2,343,164 barrels, or 32.2 per cent, a decrease of 567,697 barrels, or 19.5 per cent, from the output in 1917, a decrease due largely to diminished activity in drilling.

DEVELOPMENT.

SOUTHEASTERN AND CENTRAL OHIO.

A total of 1,695 wells was completed in southeastern and central Ohio in 1918, as compared with 1,828 in 1917. Of the wells drilled in 1918, 803, or 47.4 per cent, were oil wells with an average initial production of 15 barrels, 446 were gas wells, and 446 were dry holes. The percentage of dry holes was slightly less than in 1917. The statistics showed a marked decrease in the number of new wells in Washington County, in the Marietta and Macksburg pools, and in Jefferson and Columbiana counties. Other counties in the "shallow sand" area—Carroll, Harrison, Noble, Morgan, Belmont, Monroe, and Athens—showed increase in the number of producing wells. In the Clinton sand areas, Coshocton, Holmes, Medina, and Wayne counties showed increase in the number of new oil wells, whereas Hocking, Knox, Licking, Fairfield, Perry, and Muskingum showed decrease.

NORTHWESTERN OHIO (LIMA FIELD).

In all 416 new wells were completed in 1918, compared with 534 in 1917. Of these, 369 produced an average of 15 barrels of oil each on the first day of productive life, 9 were gas wells, and 38, or 9 per cent were dry holes. It is notable that the percentage of dry holes in this field is comparatively low and has remained fairly constant for the last 10 years at an average of a little less than 10 per cent.

Field activity in the oil districts of northwestern Ohio was confined generally to the drilling of wells in territory from which the flush production was obtained years ago and to the intensive development of restricted pools overlooked in the course of the earlier development work of the region. This type of development work

[1] Of the two areas of oil production in Ohio only the southeastern-central area belongs geographically in the Appalachian oil field, the Lima area, in northwestern Ohio, forming a part of the so-called Lima-Indiana oil field. In accordance with the custom in previous reports, however, the statistics for both areas are given here, to make the statement for Ohio cover the whole State. The Lima statistics are, of course, omitted from the tables covering the Appalachian field as a whole.

resulted in seven wells in Seneca County, and three in Wood County having initial production of 100 barrels or more.

A total of 770 wells are reported as abandoned during the year, a decrease in the number of producing wells of 401. Compared with this, 1,245 wells were abandoned in 1917, a decrease in the number of producing wells in that year of 772.

PETROLEUM PRODUCED.

[a] Includes production of Michigan.

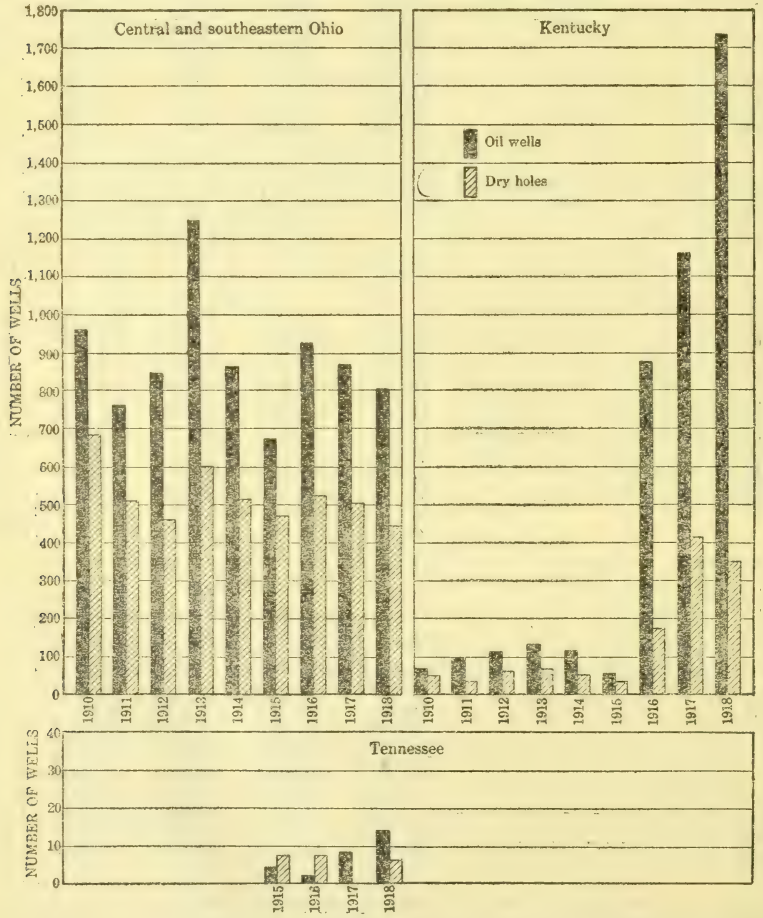

FIGURE 104.—Comparison of number of producing oil wells with dry holes drilled in central and southeastern Ohio, Kentucky, and Tennessee, 1910–1918.

SUMMARY OF WELLS DRILLED.

The statistics of field operations presented in the following tables are compiled from trade-journal sources and differ somewhat from those on pages 986–987, which are obtained from reports received directly from the oil producers.

SOUTHEASTERN AND CENTRAL DIVISION.

LIMA-INDIANA OIL FIELD.[1]

GENERAL STATEMENT.

The Lima-Indiana field embraces all areas of production of oil in northwestern Ohio and northeastern Indiana. In this field the oil occurs in low domes over the broad crest of the Cincinnati uplift or in domes, terraces, or other minor convexities on its flanks. The oil-bearing strata consist of lenses or discontinuous layers in the "Trenton" limestone, of Ordovician age, in which the original limestone has been changed to a porous dolomite. Wherever the "Trenton" limestone ceases to be dolomitic it ceases to be oil bearing. The pools in the "Trenton" rock district are very irregular in shape, differ greatly in size, and in many places entirely surround barren areas.

In southwestern Indiana there are a number of detached pools in which oil is obtained from the "Corniferous" limestone of the Devonian system and from sandstone in the Chester group of the Mississippian series (lower Carboniferous).

The Lima-Indiana oil field as a whole showed a marked decrease in production in 1918, as compared with previous years. The output of 3,220,722 barrels was less than that of 1917 by more than 12 per cent—or more than twice the rate of decline in 1917. The decline, however, was in the old Lima field, which showed a production of 2,343,164 barrels, a decrease of 19.5 per cent from the production in 1917. The Indiana fields, on the other hand, showed an increase of more than 15 per cent to 877,558 barrels. The year brought a considerable amount of development work in the old producing field in the eastern-central part of Indiana, but western Indiana, along the Illinois line in the vicinity of Princeton and Oakland City, was also active and showed an increase in production. The Oakland City field showed the most wells and the best production.

The average price per barrel received at the wells for all grades of Lima-Indiana crude was $2.31, an advance of 38 cents over the average price in 1917 and 75 cents over the average in 1916. The market value of the output in 1918—$7,450,932—was nearly 5 per cent greater than that of the output in 1917, although the quantity was 12 per cent less.

DEVELOPMENT.

New wells to the number of 693 were completed in the Lima-Indiana field during 1918, compared with 800 in 1917 and 965 in 1916. Of the wells completed in 1918, 138, or 20 per cent, were dry holes. However, 36 per cent of the wells drilled in Indiana were dry holes, as compared with only 9 per cent in the old Lima field. To offset this, the average initial daily production of the oil wells in Indiana was 27 barrels, as compared with 14.9 barrels in the Lima field.

[1] Some statistics for the Lima portion of this field are given under Ohio (pp. 1030–1032).

PETROLEUM PRODUCED.

Petroleum produced in the Lima-Indiana field in 1917 and 1918, in barrels.

INDIANA.

GENERAL STATEMENT.

Indiana showed an increase in production in 1918, the output of 877,558 barrels being greater by 118,126 barrels, or 15.5 per cent, than in 1917. This increase in production is credited to increased drilling activity, especially in the old "Trenton" area in the northeastern part of the State and to a marked decrease in the number of wells abandoned. The value of the Indiana output—$2,028,129—was greater by $557,581 in 1918 than in 1917.

DEVELOPMENT.

The greatest activity in the drilling of new wells was in the northeastern counties where the oil is obtained principally from dolomite lenses in the "Trenton" limestone. In this area 124 wells were completed, more than twice the number of completions in 1917 and more than six times the number in 1916. Of the wells drilled in

1918, 27 per cent were dry holes as compared with 47 per cent in 1917. The most marked increase in drilling activity was in Huntington, Randolph, and Delaware counties. Initial production of 100 barrels or more was reported for four wells in Delaware County and for one well in Huntington County. The largest well in the State was the George D. Roberts well No. 6 on the Tripple tract in Delaware County, which had an initial production of 200 barrels.

In the southwestern part of the State new wells were drilled in Gibson, Pike, and Sullivan counties, chief interest being centered in the vicinity of Princeton and Oakland City in Gibson County. In these three counties, however, only 152 wells were completed, as compared with 187 in 1917 and 220 in 1916.

For the State as a whole, 277 wells were completed, as compared with 266 in 1917 and 266 in 1916. Of these wells 169, or 61 per cent, were oil wells, 100 were dry holes, and 8 were gas wells; and as 135 wells were abandoned during the year, there was an increase of 34 in the number of producing oil wells.

PETROLEUM PRODUCED.

Petroleum produced in Indiana, 1914–1918, in barrels.

ILLINOIS OIL FIELD.

GENERAL STATEMENT.

The Illinois field lies wholly within the State of Illinois and includes the principal area of production of oil along the La Salle anticline in southeastern Illinois as well as a number of scattered pools of small individual extent in the central and western parts of the State. The oil in this field ranges in gravity from 28° to 40° Baumé and contains varying proportions of both asphalt and paraffin, and is obtained for the most part from sandstone and limestone layers in formations belonging to the Pennsylvanian and Mississippian series of the Carboniferous system. The productive pools on the La Salle anticline occur chiefly on the eastern flank of this arch which is asymmetrical, the western limb being much more steeply inclined than the eastern. The general oil-bearing territory extends in a slightly southeast direction from the vicinity of Westfield in northwestern Clark County through Clark and Crawford counties to the vicinity of Allendale in Wabash County. There are outliers or extensions in Coles, Cumberland, and Jasper counties, but the three counties first named have produced by far the greater portion of the oil.

Development in eastern Illinois began with a well drilled near Casey, in Clark County, which produced about 35 barrels a day from a sand found at a depth of less than 400 feet. This was in 1904, and by the end of 1905 more than a thousand barrels a day were being marketed. The maximum output of nearly 34,000,000 barrels was in 1908. Since 1910 the production has declined at an average rate of 10 per cent a year.

The production of petroleum in 1918—13,365,974 barrels—was less by 2,410,886 barrels, or 15 per cent, than the output in 1917. This very marked decrease in production was coincident with a very marked decrease in the number of new wells drilled, and a corresponding general increase in the proportion of dry holes.

The price of Illinois crude at the wells which in 1917 showed an increase from $1.62 to $2.12 a barrel continued to increase throughout the first half of 1918 to the record high price of $2.42 a barrel on July 9. This price has been maintained since that date.

Stocks of Illinois oil continued to decrease, reaching a low level of 2,366,752 barrels at the end of the year, as compared with 3,560,222 at the end of 1917 and with 6,599,972 at the end of 1916.

DEVELOPMENT.

Field activity in 1918 was less than in any year since the State began to assume importance in the petroleum industry. Only 396 new wells were completed in 1918, compared with 646 in 1917 and 1,461 in 1916. At the same time there was a marked increase in the percentage of dry holes, which amounted to 27 per cent of the total number completed in 1918, as compared with 23 per cent in 1917 and 22 per cent in 1916. The average initial yield of the 279 oil wells completed was 21 barrels. Productive oil wells were completed in nine counties and failures were reported from three, although the greater part of the drilling was in the old pools along the La Salle anticline in the southeastern part of the State. In the "shallow sand" area on this anticline only 82 wells were completed—less than half the number completed in 1917. Moreover, the percentage of dry holes rose from 14 per cent in 1916 and 1917 to 18 per cent in 1918. Most of the wells were drilled in the territory in Clark County, but this county showed a decline in average initial daily production from 12.4 to 9.3 barrels. The largest well reported from this "shallow sand" territory was the Ohio Oil Co.'s No. 1, on the Lee tract, Clark County, with an initial production of 108 barrels. In the "deep sand" area of Crawford, Lawrence, and Wabash counties 290 wells were completed, as against 437 in 1917, and of these 29 per cent were dry holes, as compared with 24 per cent in 1917. Crawford County was most active with 136 oil wells having an average initial daily production of 18.1 barrels, the highest average since 1913. Nine wells in Lawrence County and 10 in Crawford County are reported to have had an initial production of 100 barrels or more, the largest being 200 barrels from the Ohio Oil Co.'s No. 31, on the Ryan tract, Lawrence County. In the Carlyle pool in Clinton County in southern central Illinois nine wells were completed, four of which were oil wells with an average initial production of 8.7 barrels, four were dry holes, and one was a gas well. Two wells were drilled in Marion County to the east and two in Washington County, south of Clinton, all of which were dry holes. In McDonough County in western Illinois 11 wells were drilled, which were oil wells having an average initial production of 5.7 barrels.

PETROLEUM PRODUCED.

Petroleum produced in Illinois, 1889–1918.

SUMMARY OF WELLS DRILLED.

The statistics of field operations presented in the following tables are compiled from trade-journal sources and differ somewhat from those on page 987, which are obtained from reports received directly from the oil producers.

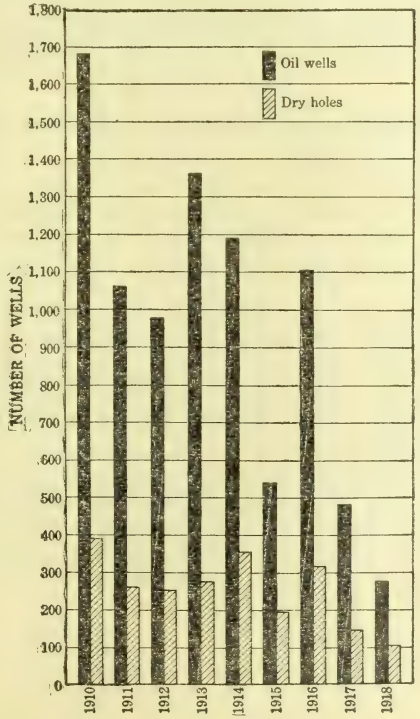

FIGURE 106.—Comparison of number of producing oil wells with dry holes drilled in the Illinois field, 1910–1918.

Wells completed in Illinois, 1914–1918.

MID-CONTINENT OIL FIELD.

GENERAL STATEMENT.

For commercial purposes it is customary to group under the title "Mid-Continent field" the areas of oil production in Kansas, Oklahoma, northern and central Texas, and northern Louisiana.[1] In Kansas, Oklahoma, and northern Texas petroleum is derived mainly from sandstone layers included in formations of the Pennsylvanian series (upper Carboniferous). In southern Oklahoma sandstone layers in the "Red Beds" of the Permian series (latest Carboniferous) form the reservoirs of oil in the Healdton district. In northern Louisiana and central Texas the oil is found in sandstones or other porous rocks belonging to the Cretaceous and Tertiary systems. The occurrence of oil throughout the Mid-Continent field is in anticlines, domes, half domes, and terraces on the flanks of major uplifts, such as the Ozark, Wichita, Arbuckle, and Sabine uplifts.

[1] Some statistics for the Texas and Louisiana portions of the Mid-Continent field are given in the sections on those States under the heading "Gulf oil field" (pp. 1076–1106).

PETROLEUM PRODUCED.

Petroleum produced in the Mid-Continent field in 1917 and 1918, in barrels.

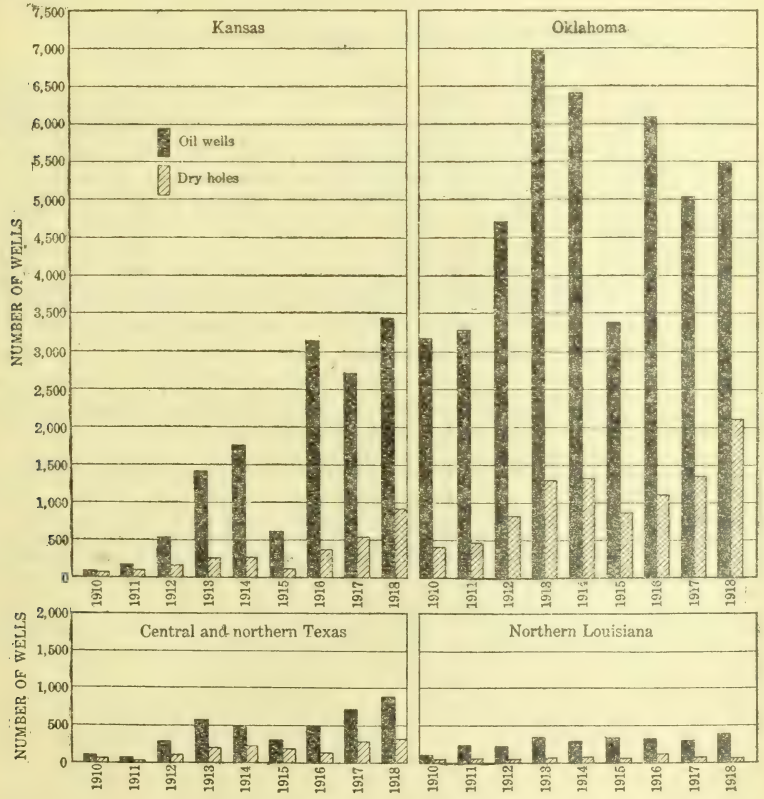

FIGURE 107.—Comparison of number of producing oil wells with dry holes drilled in the Mid-Continent field, 1910–1918.

SUMMARY OF WELLS DRILLED.

The statistics of field operations presented in the following tables are compiled from trade-journal sources and differ somewhat from those on pages 988–990, which are obtained from reports received directly from the oil producers:

Wells completed in the Mid-Continent field, 1914–1918.

KANSAS.

GENERAL STATEMENT.

The production of petroleum in Kansas in 1918 reached the record of 45,451,017 barrels, an increase of 8,914,892 barrels, or nearly 25 per cent over the output in 1917. The production increased steadily throughout the first half of the year, culminating in July, when the average daily output was 144,848 barrels. After this the production fell off rapidly, and the December output was only a little more than half that of July. The great decrease in production toward the end of the year was due to water encroachment, which cut off a large part of the oil. The large output of Kansas comes mainly from Towanda Township, in Butler County.

The average price received at the wells for this oil was $2.21 a barrel, and the total market value of the output was $100,546,202, a gain of 37 cents in average unit price and of $33,425,629, or 50 per cent, in total market value.

DEVELOPMENT.

In Kansas 4,666 new wells were reported in 1918, an increase of 1,239 wells, or 36.2 per cent over the number completed in 1917. Of the wells completed in 1918, 3,458 were classed as oil wells with an average initial output of 96.9 barrels per day, 269 were gas wells, and 939 were dry holes. The percentage of dry holes to total wells drilled was 20.1 per cent, as compared with 15.7 per cent in 1917 and only 10.2 per cent in 1916.

There was a general increase of activity in the search for new pools and in intensive drilling of old pools and the increase in drilling activity extended over a large part of the State.

Butler County.—During the first part of the year Butler County and in particular the Towanda pool, was the most promising spot in the Mid-Continent field. A number of wells of large capacity had been drilled, and their production was holding up remarkably well. The Shumway lease of the Gypsy Oil Co., sec. 11, T. 26 S., R. 4 E., in the center of the pool, was the best producing lease, and the Shumway well No. 5, completed in September, 1917, was the largest well in the Mid-Continent field and was reported to have an initial output of 26,000 barrels a day. In March, 1918, six months after completion, it was still making 12,000 barrels daily. A number of large wells were drilled in this pool in the early part of the year, but in April a number of the wells began producing salt water and No. 5 on the Shumway lease stopped flowing. By September many wells had been drowned out. The methods of excluding water commonly practiced in the Mid-Continent field having proved inadequate, the outlook at the end of the year was very discouraging.

Early in the year the completion of good wells in sec. 25, T. 26 S., R. 4 E., and in secs. 29 and 32, T. 26 S., R. 5 E., marked an extension of the south end of the Eldorado pool, and a 500-barrel well in the NW. ¼ sec. 2, T. 25 S., R. 5 E., in February extended the Eldorado pool half a mile to the northeast.

Much interest was attracted to what promised to be a new and important pool in northwestern Butler County approximately 18 miles north and a little west of the Eldorado pool, where the Elbing Oil & Gas Co. got a well rated at 400 barrels initial daily production in sec. 18, T. 23 S., R. 4 E., at a depth of about 2,440 feet. This well was 9 miles from the nearest producing well at Potwin. Other tests in this district were poor or were complete failures, and at the end of the year the district showed little promise.

Greenwood County.—Greenwood County, east of Butler County, was thoroughly prospected in 1918. A total of 186 wells was completed, of which 101 were rated as oil wells and 80, or 43 per cent, were dry holes. This county has proved very "spotted" and the large percentage of dry holes has proved discouraging.

PETROLEUM PRODUCED.

Petroleum produced in Kansas, 1914–1918, in barrels.

OKLAHOMA.

GENERAL STATEMENT.

For the fourth consecutive year Oklahoma held first rank among the oil-producing States. The total production in 1918 was 103,347,070 barrels, a decrease of 4,160,401 barrels, or 3.87 per cent from the record output of 1917.

A normal decrease in production is shown in the reports from the Glenn, Cushing, and Healdton pools and from Osage County, which is, however, practically offset by increased production from the newer pools, particularly from Okmulgee County and from the Garber and Billings pools.

The average price received at the wells for the petroleum marketed in Oklahoma in 1918 was $2.24 a barrel, and the market value of the output was $231,136,205, a gain of 55 cents in average unit price and of $49,489,224, or 27 per cent, in the total market value of the oil sold, compared with 1917.

A total of 8,376 wells were completed in Oklahoma in 1918, an increase of 1,579, as compared with 1917. This was the largest number of wells drilled in the State since 1913, when the record number was 8,851 wells. Of the wells drilled in 1918, 5,495 were oil wells credited with an average yield of 68.4 barrels for the first day of productive life, 762 were gas wells, and 2,119 were dry holes. The average initial production was lower in 1918 than in any year since 1913 and the percentage of dry holes, 25 per cent, was greater than in any other recent year. The percentage of dry holes to total wells drilled in each of the last nine years was as follows:

Percentage of dry holes to total oil wells drilled in Oklahoma, 1910–1918.

	Percentage of total.		Percentage of total.
1910	11	1915	19
1911	12	1916	15
1912	14	1917	20
1913	15	1918	25
1914	16		

DEVELOPMENT.

NORTHEASTERN OKLAHOMA.

Cherokee district.—The increased price of crude oil resulted in renewed activity in drilling both in the shallow sand division in Craig, Nowata, and northern Rogers counties and in the deep sand division in Washington, western Rogers, and northern Tulsa counties. No new territory of importance was opened in this district. The record is discouraging in that the increase in drilling activity resulted in a slight increase in the percentage of dry holes and in a decrease in average initial yield in both the shallow and the deep sand divisions.

Osage district.—Osage County was one of the centers of interest in Oklahoma in 1918. The total number of wells reported in the trade periodicals was 1,375, more than twice the number reported in 1917, and nearly five times the number reported in 1916. The search for new territory was extremely active, resulting in a marked increase in the percentage of dry holes—18.6 per cent as compared with 10 per cent in 1917 and 1916. The average initial daily yield of new wells was also much less than in other recent years. The production from Osage County as reported by the Commissioner of Indian Affairs from the records of the agency at Pawhuska was 10,634,076 barrels in 1918, a decrease of 5.18 per cent as compared with 1917. The decrease in production as well as in average initial yield of new wells is attributed to the decrease in productivity of the Osage-Hominy and Boston pools.

The most important discovery of the year was well No. 2 of the American Pipe Line Co. on a gas lease in sec. 17, T. 27 N., R. 8 E., in new territory in the western half of the county. The well was reported to have had an initial production of about 5,000 barrels. The oil lease of the quarter section was sold on November 9 to the Gypsy Oil Co. and, according to trade reports, the well flowed 3,400 barrels the first 24 hours after being connected to a pipe line. The oil was struck at a depth of 2,408 feet in what was reported to be the "Mississippi lime."

Kay County.—The Blackwell pool in Kay County continued to increase in importance in both the shallow and the deep sands. The shallow sand continued to furnish the bulk of the output but a number of deep wells were completed during the year, extending the area of deep sand production very materially. One well in sec. 17, T. 28 N., R. 1 E., drilled by the Southwestern Oil Co. was reported to have started producing at the rate of 1,300 barrels a day.

Attention was attracted to the deep sand possibilities in the Newkirk and Ponca City territory by the drilling in of a small well in sec. 34, T. 27 N., R. 3 E., about the middle of 1917. Other tests scattered over an area some 13 or 14 miles long and 3 or 4 miles wide got good showings of oil. In June, 1918, exceptionally good wells were completed in sec. 15, T. 27 N., R. 3 E., by the Carter Oil Co. and by James J. McGraw and associates. One of these wells started flowing at the rate of 2,000 barrels or more a day. The oil sand is found at approximately 3,100 feet. Later drilling, however, showed this deep sand pool to be limited in extent.

Noble County.—The Billings pool which was opened up in 1917 continued to bring in wells of large initial capacity throughout the first half of the year. The two best wells reported were in sec. 15, T. 23 N., R. 2 W.—one by the Humphreys Petroleum Co., with an initial daily output of 4,000 barrels, and one by the Mid-Co Petroleum Co., which for a short time produced as high as 5,000 barrels daily. By the end of May the production from this pool was reported to be approximately 14,000 barrels from 21 wells, all of the production coming from a sand at approximately 2,100 feet. Outside tests around the Billings pool, however, failed to increase the productive area and the pool appears to be very limited in extent.

A deep test, reported to be the deepest in northern Oklahoma, was drilled by the Humphreys Petroleum Co. in sec. 29, T. 24 N., R. 1 W., and obtained a showing of oil at 4,334 feet.

Garfield County.—Development in the Garber pool was marked by the discovery of a number of new sands. In December it was reported that at least ten oil sands had been penetrated between 100 and 2,300 feet in depth. This, however, may be an exaggeration inasmuch as there is considerable uncertainty concerning the correlation of the productive sands. The sand found at 2,100 feet—the Garber sand—was reported to be proved around the edges of a territory 3 miles long and 9 miles wide. The upper sands are not productive over so large a territory. The Garber pool is distinctly different from the Billings pool 10 miles northeast in that the Billings pool has furnished a number of very large wells from a small area and from a single sand, whereas the Garber pool has furnished a much larger number of wells with much smaller average production and from a number of different horizons. In the Garber pool the most regular producing sands in 1918 were the Hoy sand at 1,100 feet, the Hotson at 1,500 feet, and the Belveal at 1,750 feet. Indications at the end of the year showed that the sands at 2,100 to 2,300 feet had a much larger producing area than the shallower sands.

Between the Garber and the Billings pools in sec. 15, T. 23 N., R. 2 W., the Oil States Petroleum Co. brought in a 40-barrel well in April at 2,040 feet, which attracted considerable interest as a possibly important new pool.

Four miles east of Garber in sec. 22, T. 22 N., R. 3 W., the Bear Creek Oil Co. got a showing of oil in October.

Payne County.—The Yale-Gray district continued to furnish a number of good wells throughout 1918. Drilling was active, with 73 per cent more wells completed than in 1917, but no new territory of importance was discovered and the average initial production of new wells declined from 395 barrels in 1917 to 137 barrels in 1918.

Creek Nation.—The territory allotted to the Creek Nation includes the counties of Creek, Okmulgee, Muskogee, Wagoner, Okfuskee, and part of Tulsa and embraces the famous Glenn and Cushing pools, as well as a large number of smaller pools.

The total completions of new wells from the Creek district in 1918 was 3,567, an increase of 183, or 5 per cent, over the number drilled in 1917. The average initial production of new wells was considerably higher than in 1917 but not nearly so high as in other recent years.

In Creek County, which includes the famous Cushing and Glenn pools, drilling activity was slightly less than in 1917 and little new territory of importance was discovered. A well drilled by the Eastern Oil Co. in sec. 3, T. 17 N., R. 10 E., near Kellyville, promised an extension of the Kellyville pool and started producing at the rate of 600 barrels a day. A test by the Wolverine Oil Co. in sec. 34, T. 18 N., R. 9 E., 6 miles west of the Kellyville pool started producing 25 to 35 barrels from a sand at a depth of 1,935 feet, but the production declined very rapidly.

In Tulsa County promising territory was opened up near Sand Springs. A well drilled by the Phoenix Refining Co. in sec. 5, T. 19 N., R. 11 E., late in April was rated at 2,400 barrels a day but declined rapidly.

In Wagoner County new wells with initial production of 100 to 600 barrels per day were completed in sec. 29, T. 17 N., R. 15 E., north of the Stone Bluff pool.

Okmulgee County was noted in oil history in 1918 because of a number of small but very rich pools. These were for the most part found as the result of deep tests drilled in older producing territory. The most prominent was the Youngstown pool in secs. 25 and 36, T. 14 N., R. 11 E., later extended into secs. 1 and 2, T. 13 N., R. 11 E. The pool was discovered as a result of the deepening of an old well on the Huckaby tract in sec. 25 in December, 1917. A number of wells with initial daily capacities of 500 to 2,500 barrels followed in the early spring, but the pool was quickly defined by dry holes around the borders and only a few large wells were completed in the last half of the year. The oil was found at depths of 2,200 to 2,300 feet. The discovery of the Youngstown pool caused considerable deep drilling in Okmulgee County. Scattered production was found in a number of places but the territory has proved "spotted," the individual pools being small but prolific. One of the most promising of the small pools is in sec. 9, T. 13 N., R. 12 E., where wells of 300 to 500 barrels initial daily capacity were found at a depth of approximately 2,700 feet. North of Youngstown in sec. 36, T. 15 N., R. 11 E., at Hamilton Switch, wells of 500 to 1,500 barrels initial production were brought in in the latter part of the summer at a depth of about 2,400 feet.

Other wells of particular interest in Okmulgee County included a 1,400-barrel well in sec. 27, T. 13 N., R. 11 E., at a depth of 2,289 feet and a 1,800-barrel well in the Booch sand in sec. 25, T. 14 N., R. 14 E., in the Bald Hill pool. Both wells were exceptionally large.

The Mounds pool in Tulsa County was active in the early part of the year with several large producers but later attracted little attention. The prolific area in this pool proved to be small and "spotted."

Drilling was active in Muskogee County during 1918 but the new territory opened up consisted in only small pools or extensions of old pools. A small pool in sec. 2, T. 14 N., R. 15 E., midway between Boynton and Haskell, had a good completion in April at about 1,600 feet. The old Sheppard pool had some good completions early in the year, but this, like other pools in Muskogee County, has furnished as a rule only small pumpers with an occasional good well.

SOUTHWESTERN OKLAHOMA.

Carter County.—The production of the Healdton field in 1918 was 15,695,322 barrels, a decline of 2,658,208 barrels, as compared with the record output of 1917. There was a very marked decline in the number of new wells drilled in Carter County, only 272 in 1918 as compared with 519 in 1917. The percentage of dry holes in 1918 was more than 25 per cent, as compared with 9 per cent in 1917 and only 2.5 per cent in 1916. The initial daily capacity of new wells declined from 95 barrels in 1917 to 57.9 barrels in 1918. These records show clearly the exhaustion of the rich possibilities of the Healdton pool.

A large quantity of oil was run into storage in the Healdton field in 1916 and 1917 and the draft from this reserve was very large in 1918.

Near the beginning of the year it was reported that approximately 1,800 wells were producing from the Healdton pool and that new wells were being drilled rapidly. Efforts during the year, however,

to discover extensions of the pool or to obtain production from deeper sands met with some success, but nothing of great importance was developed.

A well drilled by the Gates Oil Co. in sec. 14, T. 4 S., R. 3 W., to a depth of 3,600 feet in the search for deep productive sand was reported abandoned as a failure. The Fox pool located in T. 2 S., R. 3 W., was developed in 1917 as a rich gas pool of particular interest in 1918. Six or seven miles to the northeast of the Fox pool, in sec. 7, T. 2 S., R. 2 W., the Oklahoma-Fox Oil Co. got a well at 2,500 feet rated at from 200 to 500 barrels.

Cotton and Stephens counties.—The well of the Magnolia Oil Co. in western Stephens County, in sec. 22, T. 1 S., R. 9 W., together with showings of oil in several near-by tests of about the same depth in Cotton and Stephens counties attracted more attention than any discovery since that of the Billings pool. The Magnolia well reached the oil sand at a depth of 2,340 feet in May, 1918, and started flowing at a rate of 200 barrels a day. Later the well was deepened and the rate of flow was temporarily increased to about 400 barrels. This locality is about 30 miles northwest of the Healdton pool and 45 miles northeast of the fields in Wichita County, Tex. In the vicinity are a number of old shallow wells, some of which were drilled years ago but did not produce oil in commercial quantities. The Magnolia Oil Co.'s well is a thousand feet or more deeper than these old wells.

In T. 1 S., R. 10 W., 7 miles southwest of the Magnolia well is the Keyes gas field opened up in 1917, in which a small quantity of oil was found.

In sec. 3, T. 2 S., R. 10 W., on the eastern edge of Cotton County, approximately 7 miles southwest of the Magnolia well, the Wichita Fuel Development Co. got a good well in what appeared to be the same sand at a depth of 2,300 feet.

In sec. 29, T. 1 S., R. 10 W., approximately 10 miles west of the Magnolia well, a small flow of oil was encountered at 2,409 feet.

These discoveries attracted much attention to southwestern Oklahoma and drilling was active throughout the later part of the year. Stephens County was credited with a total of 133 wells completed, of which 75 were rated as oil wells, and Cotton County had 48 completions, of which 22 were oil wells. Most of these wells, however, were of small capacity and no pools of major importance were discovered.

PETROLEUM PRODUCED.

Petroleum produced in Oklahoma in 1917 and 1918, in barrels.

GULF OIL FIELD.

GENERAL STATEMENT.

The term "Gulf field" as used in this report includes that portion of the Gulf Coastal Plain of Texas and Louisiana in which petroleum is found in domes, associated with rock salt and gypsum. In this area the age of the oil-bearing strata ranges from Cretaceous to Quaternary and the reservoir rock is generally either porous dolomitic limestone or sandstone.

The output of petroleum in the Gulf field in 1918 was 24,207,620 barrels, a decrease of 135,259 barrels, or 0.56 per cent, as compared with the output in 1917. The average price received at the wells was $1.70 a barrel and the market value of the entire output was $41,053,846, a gain of 63 cents a barrel in the average unit price and of $14,966,259, or 57 per cent, in total value, compared with 1917. The market value of the output in 1918 was greater than that of the output in any other year in the history of the Gulf field, and the average price per barrel at the wells was higher than in any other year since 1899, when the entire production amounted to only 530 barrels and consisted of lubricating oil obtained from shallow wells in Hardin and Nacogdoches counties, Tex.

The "posted" or open-market price for the leading grades of oil produced in the Gulf field, which was advanced to $1.80 a barrel on December 30, 1917, remained essentially unchanged throughout 1918.

Despite the increase in price of oil there was a slight decrease in the number of the wells completed, as compared with 1917. In 1918, 1,443 wells were completed in the Gulf field, of which 955 were oil wells, with an average initial output of 331.9 barrels per day, 24 wells produced gas only, and 464, or 32 per cent, were dry holes. The field as a whole showed a marked decrease in the percentage of dry holes and at the same time a corresponding decrease in the average initial production of new wells.

The principal features of the industry in the Gulf field include the discovery of new sources of oil at West Columbia in Brazoria County and at Hull in Liberty County. Wildcat drilling was fairly active but was much curtailed by lack of drilling supplies.

PETROLEUM PRODUCED.

Petroleum produced in the Gulf field in 1917 and 1918, in barrels.

TEXAS.

GENERAL STATEMENT.

Petroleum marketed in Texas from field sources in 1918 amounted to 38,750,031 barrels, an increase of 6,336,744 barrels, or 19.55 per cent, over the output in 1917. Of this record output the stratum division, including the oil districts of central and northern Texas, which are classified as part of the Mid-Continent field (see pp. 1052–1059), contributed 17,280,612 barrels, or 44.6 per cent of the total, and the salt-dome division of the Gulf Coastal field, including the oil fields of southeastern Texas, contributed 21,469,419 barrels, or 55.4 per cent. The increase is credited largely to the newly developed fields of north-central and northern Texas—Ranger, Breckenridge, and Burkburnett. The actual output of the wells in these new fields was probably somewhat larger than the quantity marketed; the difference, however, was undoubtedly small, inasmuch as the marketing companies were able to take care of the greater part of the production either by pipe-line or railway shipments or by the construction of storage facilities near the points of production.

The average price received at the wells for all grades of oil marketed in Texas in 1918 was $1.93 a barrel, a gain of 61 cents in average unit price compared with 1917. The market value of the crude oil sold in 1918 was $74,867,537, a gain of $31,975,982, or 75 per cent, over the market value of the output in 1917. Of this sum the share credited to the stratum division was $38,313,019, or 51.2 per cent, and that to the salt-dome division was $36,554,518, or 48.8 per cent, the average unit price in the stratum division being $2.22 a barrel—39 cents higher than in 1917—and in the salt-dome division being $1.70 a barrel—64 cents higher than in 1917.

DEVELOPMENT.

The drilling of new wells in 1918 was stimulated by increase in prices and by the discovery late in 1917 of new and promising pools in Eastland, Stephens, and Brown counties. Development was, however, much retarded by greatly increased cost of drilling material, lack of storage facilities, congestion of railway transportation, scarcity of labor, scarcity of water, and in the latter part of the year by the epidemic of influenza. In all, 2,468 wells primarily for petroleum were drilled in Texas in 1918, an increase of 87 over the number drilled in 1917. Of these 1,729 were classed as oil wells with an average initial production of 247.3 barrels daily, 46 produced gas only, and 693, or 28 per cent, were dry holes.

STRATUM DIVISION.

In central and northern Texas a total of 1,219 wells were completed in 1918, of which 891 were classed as oil wells, with an average initial production of 165.4 barrels per day, 24 produced gas only, and 304 were dry holes. As compared with 1917, the year marked a decided increase in production and in number of new wells drilled, a decrease in the percentage of dry holes, and more than 100 per cent increase in the average initial yield of new oil wells.

The features of outstanding importance were the gradual development of the deep-sand pools in Eastland and Stephens counties, the rapid development of the shallow-sand pool at Brownwood in Brown County, the discovery and rapid development of a very prolific pool largely within the town limits of Burkburnett in Wichita County, and the discovery of the Duke pool in Comanche County. The discovery and development of these prolific pools attracted general attention to the Texas fields, and an extensive campaign for the discovery of new territory was inaugurated. Activity spread from these centers throughout all of central and western Texas. Operations were greatly retarded in 1918, but an enormous increase in drilling activity was promised for 1919.

Wichita County.—Wichita County showed a marked increase in production, in the number of new wells drilled, and in the average initial yield of new wells in 1918, as compared with 1917. The older producing areas at Electra and southwest of Burkburnett combined to furnish good producers throughout 1918. The newer development at Sunshine Hill, 6 miles northeast of the Electra pool, attracted considerable attention during the early part of the year. In April this pool was reported to have 75 producing wells in an area of about 50 acres. The principal producing sand was reached at about 500 feet. The Ramming pool, approximately 3 miles east of Sunshine Hill, was reported in April to have 216 wells producing from a depth of about 1,700 feet.

In the last week of July the Fowler Oil Co. brought in a well reported to have started flowing at 2,500 to 4,000 barrels daily at the north edge of Burkburnett town site, some miles from the nearest productive territory. The oil was found at a depth of 1,735 feet. A campaign of town lot development immediately ensued. The drilling campaign was carried out largely by small local companies and a large number of wells were drilled in a comparatively small area. The area proved very prolific; the majority of the wells

started flowing at 100 to 500 barrels a day, but several wells started at 1,000 to 3,000 barrels daily.

In the Iowa Park field, south and west of Iowa Park, new territory was opened up by the completion of wells on the Watkins farm. Before the end of the year this shallow pool furnished a number of good producers.

In April, 1918, Electra field was reported to have 1,199 producing wells, Burkburnett 918, Sunshine Hill 75, Iowa Park 56, and Holliday 11.

Clay County.—The Petrolia field in Clay County attracted little attention during 1918. Production declined markedly and only 11 wells were completed in the county, of which 6 were dry holes. In April the Petrolia pool was reported to have 502 producing wells.

North-central Texas.

The petroleum fields in north-central Texas include those of Eastland, Stephens, Brown, Comanche, Shackelford, and Palo Pinto counties, and prospective territory in adjoining counties. The shallow pools of Strawn, Moran, and Brownwood are included in the north-central Texas field as well as the deep-sand pools of Ranger, Breckenridge, Caddo, and Duke. Throughout the greater part of the year the deep-sand pools, of which the Ranger pool is the most extensively developed, became the central interest among the oil operators not only in Texas but in the whole country. Toward the latter part of the year the interest was divided between the country centering around Ranger and the Burkburnett district in Wichita County. The oil in the deep-sand pools is obtained from several different horizons in the so-called Bend series, which is of Pennsylvanian and Mississippian age.

The J. H. McClesky well, of the Texas Pacific Coal & Oil Co., near the town of Ranger, which was completed on October 25, 1917, was the discovery well of the Ranger pool and marked the beginning of the intensive development of the deep-sand territory. This well started flowing at the rate of 1,200 barrels a day. The Parks well in the vicinity of Breckenridge in Stephens County was, however, the first well which produced oil from the Bend.

The Ranger pool proper lies in northeastern Eastland County, in and to the west of the town of Ranger. The oil is obtained at depths of from 3,200 to 3,500 feet from the sandy lenses in the Marble Falls limestone. Up to March 20, 1918, the district had 4 producing wells, all the property of the Texas Pacific Coal & Oil Co. The Davenport well, an offset to the discovery well, came in on March 13, flowing at the rate of 1,000 barrels a day, and the Hegaman well, northeast of the town, developed a production of 200 barrels a day on March 14.

The Walker well, at the edge of the town of Ranger, was first rated as a gasser but gradually developed into a producing oil well. Interest in the field was greatly extended by the bringing in 4 miles south of Ranger, in June, of the Brewer well No. 1, with a reported initial production of 3,200 barrels a day, and by the Jones well, west of Ranger, which was completed in July, with an initial production of 4,500 barrels. The largest well drilled during the year, however, was the No. 1 Emma Terrill, of the Prairie Oil & Gas Co., which was credited with an initial yield of 11,000 barrels a day. By the end of the year producing wells were scattered over an area of approximately 25

square miles. About 50 wells were producing oil, approximately 20 wells were shut down on the top of the sand awaiting storage, 50 wells were drilling below 3,300 feet, and 80 additional wells had been started. During the year a total of 88 completed wells was credited to Eastland County, of which 62 were classed as producing oil wells having an average initial production of more than 1,000 barrels a day.

Eight miles east of Ranger, on the Allen Ranch, the Sun Co. drilled to the top of the Ranger sand, where the tools were lost and never recovered. With the sand just entered at 3,037 feet, the well started flowing 300 barrels daily, of which 50 per cent was oil and 50 per cent salt water. At the end of the year this territory looked very promising.

Near Olden Switch, midway between Ranger and Eastland, several wells of small capacity were obtained in a sand about 1,350 feet below the surface. These wells gave promise of a good shallow pool, but received scanty attention on account of the greater promise from the deep sands. A total of 21 dry holes was reported from Eastland County in 1918, most of which were drilled in wildcat territory in the hope of obtaining extensions of the Ranger pool.

Stephens County.—The Breckenridge pool in Stephens County, 4½ miles south of the town of Breckenridge, was developed around the original Parks well, which was drilled in 1916, but no extensive drilling campaign was begun until after the Ranger discovery, so that the real development was actually the result of that of Ranger. At the end of the year this pool contained 10 producing wells of which the more important were the Lauderdale, which started flowing 1,000 barrels a day, and the Fincher No. 2, which was producing 2,200 barrels daily one week after being drilled in. At the end of the year there were 44 locations or wells drilling in the vicinity of the Breckenridge pool, scattered over an area of 4 by 10 miles.

The Caddo pool, extending southwesterly from the town of Caddo which is 12 miles east of Breckenridge, was discovered during the year 1918 and at the end of the year had 5 producing oil wells, 2 gas wells, and 2 dry holes, in addition to 30 locations and wells drilling. The most important well was the Sandidge well of the Texas Co., which started flowing at the rate of 1,000 barrels a day. The Veale pool, 9 miles south of Caddo, centers around the Veale well of the Texas Pacific Coal & Oil Co. In this well a 20-foot gas sand was found at a depth of 3,960 feet which produced several million cubic feet of gas and a little oil. The production of oil increased greatly and at the end of the year the well was flowing 500 barrels a day. The only other producing well in this pool at the end of the year was the Sudderth, 2 miles west of the Veale. There were, however, 4 producing gas wells and 28 locations or wells drilling scattered over an area of 50 square miles around the Veale well as the center. Much attention was attracted to the well of the Texas Co., on the ranch of the Black Bros., 4½ miles east and 12 miles north from the town of Breckenridge. This well struck oil in the Smithwick shale and started flowing at 200 barrels a day.

Comanche County.—One of the most important discovery wells of the year was the Duke well in northern Comanche County near the eastern county line, which was completed on September 2, 1918. At the end of the year 2 wells had been completed in this pool, of

which the Knowles well, an offset to the Duke, was the larger. This well started flowing at the rate of 4,500 barrels a day.

Brown County.—The shallow pool at Brownwood in Brown County was intensively developed in the early part of the year. The wells listed in the trade journals as in Brown County numbered only 105 for the year 1918 and 4 for 1917, but apparently a great many small wells were completed which were not listed, inasmuch as a news report of May 16, 1918, states that 319 wells were producing at that time and that at least 40 wells were finished and had not been placed on the pump. The wells were all small but were profitable on account of the very shallow depth—150 to 300 feet—to which it was necessary to drill. Interest in this pool declined after the middle of the year, and only 7 completions are reported for the last four months.

In addition to the promising pools developed in northern central Texas in 1918, several good showings of oil or gas were found at scattered localities which for a time at least seemed to promise new productive pools. Particular interest was centered in northeastern Coleman County and in the deep-sand possibilities of Brown County. According to news reports, the Magnolia Oil Co. completed 2 tests on the Morris tract, in northeastern Coleman County, which started flowing approximately 120 barrels a day each. On the Walter Gray farm, also in northeastern Coleman County, Mitchell Bros. obtained oil at a depth of 2,145 feet. The well was reported to have started flowing at the rate of 150 barrels a day.

An important test by the Pecan Bayou Oil Co., on the Matlock farm southeast of Brownwood, obtained a strong flow of gas at a depth of 2,300 feet. A test of the Tidal Oil Co., on the Underwood farm, 16 miles south of Ranger, was reported in July to have a showing of light-green oil. In August it was reported that the test of the Texas Co., on the Graham farm, 13 miles west of Graham in Young County, had reached an oil sand at 3,606 feet and was producing 40 barrels a day.

The following is a list of dry holes abandoned in 1918 as reported in the January, 1919, number of the Oil Trade Journal:

EASTLAND COUNTY.

Atlas Oil Co.; No. 1 Mann; in the northeast corner of sec. 4, T. Mullrune survey; depth, 3,500 feet.
Beaver Valley Oil & Gas Co., No. 1 Lyons; F. Blundell survey; depth, 3,480 feet.
Cunningham et al; No. 1 R. T. Riddle, 12 acres; F. Blundell survey; depth, 3,520 feet.
Humble Oil & Refining Co.; No. 1 Patton; depth, 3,500 feet.
Havemeyer & Seaman, No. 1 Alsobrook; block 1, sec. 14, H. and T. C. survey, No. 200; depth, 3,525 feet.
Mid-Kansas Oil & Gas Co.; No. 1 J. R. Jackson; 330 feet east and 330 feet south of center of block 4, sec. 66, T. P. survey, 5 miles southeast of Caddo; depth, 3,745 feet.
Prairie Oil & Gas Co.; No. 1 Jack Phillips; J. Bledsoe survey, 2 miles southeast of Ranger; depth, 4,210 feet.
Prairie Oil & Gas Co.; No. 1 Falls; 4 miles south of Ranger; abandoned at 4,000 feet.
Prairie Oil & Gas Co.; No. 1 Vick; James Lehea survey, 1 mile east of Ranger; depth, 3,525 feet.
Sammies Oil Co.; No. 1 Dean; northeast corner of 2-acre tract, F. Blundell survey; depth, 3,709 feet.
System Oil Co. (Tidal Oil Co.); No. 1 E. R. Underwood; O. S. Richardson survey, 9 miles southeast of Ranger; depth, 3,584 feet.
Texas Pacific Co.; No. 1 W. S. Davenport; depth, 3,700 feet.
Texas Pacific Co.; No. 1 V. V. Cooper; Wm. Frels survey; depth, 3,750 feet.

Texas Pacific Co.; No. 2 W. R. Hodges heirs; F. Blundell survey; abandoned at 325 feet on account of Sammies Oil Co.'s offset on Dean being dry.
Texas Pacific Co.; No. 1 J. M. Rusk; depth, 3,800 feet.
Texas Pacific Co.; No. 1 Eva McDowell; F. Blundell survey, northwest part of Ranger; depth, 3,508 feet.
Texas Pacific Co.; No. 1 Pitcock; Wm. Frels survey, ½ mile south of Ranger; depth, 4,020 feet.
Texas Pacific Co.; No. 1 Lane; depth, 3,505 feet.

STEPHENS COUNTY.

Gulf Production Co.; No. 1 A. M. Fincher; in northwest corner northwest ¼ block 6, sec. 12, T. P. survey, 5½ miles southeast of Breckenridge; depth, 3,775 feet.
Texas Pacific Co.; No. 1 Barrow; northeast corner G. W. Dolley survey; depth, 3,583 feet.
Texas Pacific Co.; No. 1 Booher; 300 feet each way from northwest corner southeast ¼ block 7, sec. 28, T. P. survey; depth, 3,445 feet.
Texas Pacific Co.; No. 1 W. H. Corbett; near middle of west line of T. E. & L. survey; depth, 2,165 feet.
Texas Pacific Co.; No. 1 Gantt; 1 mile south of Caddo; depth, 3,360 feet.
Texas Pacific Co.; No. 1 Hughes; northwest corner A. B. & M. A. survey; depth, 2,360 feet.
Texas Pacific Co.; No. 1 T. D. Lauderdale; northwest corner block 6, sec. 38, T. P. survey; depth, 1,975 feet.
Texas Pacific Co.; No. 1 Mrs. McNabb (Lacasa); 250 feet southwest from southeast corner of block 4, sec. 69, about 7 miles southeast of Caddo; depth, 1,800 feet.
Texas Pacific Co.; No. 1 Porter Brown (Lacasa); block (?), sec. 90, T. P. survey; depth, 3,510 feet.
Texas Pacific Co.; No. 1 Wright; block 5, sec. 43, ½ mile southwest of Caddo; depth, 3,550 feet.
Texas Co.; No. 1 Keathley; 990 feet south 312 east from northwest corner T. E. & L. survey No. 3357, 6 miles southeast of Breckenridge; depth, 3,326 feet. (Reported to have resumed drilling in this test.)

COLEMAN COUNTY.

Graham, Ludlow & Thomas; No. 1 Abney; Kerr County school lands; depth, 2,611 feet.
Magnolia Petroleum Co.; No. 1 Sealy; John Sealy survey, 11 miles northeast of Coleman; depth, 3,620 feet.
Magnolia; 4 Morris ranch; David Breeding survey No. 728; depth, 3,980 feet.
Mutual Petroleum Co.; No. 1 Babbington; sec. 279, E. T. survey; depth, 2,330 feet.
Skelley & Sankey; No. 1 Gray; Mark Isod survey; depth, 2,000 feet.
Wood & Wooley; Burnet County school lands; depth, 1,520 feet.

CONCHO COUNTY.

Schultz Oil Co.; No. 1 M. Swenson; block 12, T. & N. O. survey; depth, 1,430 feet.

PALO PINTO COUNTY.

Empire Gas & Fuel Co.; No. 1 Watson; Daniel Brooks survey, 8 miles northwest of Palo Pinto town; depth, 4,065 feet.
Empire Gas & Fuel Co.; No. 1 Watson; Daniel Brooks survey; depth, 4,059 feet.
E. G. Johnson et al.; No. 1 Smith; block A, sec. 14, T. P. survey; depth, 4,400 feet.
Owen & Wilson; No. 1 John Oakes; 165 acres, Robert Evans survey, 6 miles southwest of Mineral Wells; depth, 4,450 feet.
Slim Jim Oil Co.; No. 1 R. P. Lee; T. E. & L. survey, 3 miles northwest of Graford; depth, 2,250 feet.
Texas Pacific Co.; No. 1 Gillespie; 27 acres, John Bird survey, 9 miles south of Palo Pinto town; depth, 1,505 feet.
Texas Pacific Co.; No. 2 Wilbar; M. Latham survey, 1,560 feet south of No. 1; depth, 1,817 feet.

COKE COUNTY.

Robert Lee Oil Co.; No. 1 Locke; Carl E. Hohlre survey; depth, 2,110 feet.
W. W. Skinner et al.; No. 1 McCabe survey No. 31; depth, 700 feet.

PARKER COUNTY.

Texas Pacific Co.; No. 1 Rock Creek; sec. 375, M. E. P. & P. survey; depth, 3,615 feet.

ERATH COUNTY.

Texas Pacific Co.; No. 1 Long; John McLennan survey; depth, 3,435 feet.

BROWN COUNTY.

Collins et al.; No. 1 Greeley; R. Rose survey; depth, 1,590 feet.
Hart & Son; No. 4 Coyle; R. W. Shannon survey; depth, 2,038 feet.
Oil States Petroleum Co.; No. 1 Alvis; 100 feet east 300 feet north from southwest corner northeast ¼ sec. 37, 18 miles northwest of Brownwood; depth, 3,160 feet.

MONTAGUE COUNTY.

Four-in-One Oil Co.; No. 1 Mays; Belcher subdivision; depth, 700 feet.

Central Texas.

Development in the Corsicana and Powell districts, Navarro County, and in the Thrall district, Williamson County, was practically at a standstill during 1918 and the production from these pools showed a normal decline. According to a new report in June, Navarro County had 953 producing wells with an average output of 1 barrel per day per well.

Eastern Texas.

In Panola County, where disappointing results were reported in 1917, of a total of 6 wells drilled in 1918 only 1 was reported as an oil well. Better results were obtained in Shelby County where 4 wells were reported as completed, all of which were rated as producers.

SALT-DOME DIVISION.

Coastal Texas.

The output of crude petroleum from the producing districts of the salt-dome division of southeastern Texas in 1918 was 21,469,419 barrels, a slight decrease from the output in 1917. The market value, however—$36,554,518—was greater by $13,615,628, or 59 per cent, than the value of the output in 1917.

Damon Mound, Goose Creek, Saratoga, and Spindletop increased their productive capacity during the year, while Humble, Sourlake, and other smaller pools decreased considerably. There were 1,249 wells drilled primarily for oil during the year as compared with 1,336 drilled in 1917. Of the wells drilled, 838 were rated as oil wells, with an average initial output of 334.4 barrels a day, 22 wells produced gas only, and 389 wells were rated as dry holes. The total showed a slight reduction in production and in total number of new wells drilled, an increase, however, in the number of oil wells completed, and a marked decrease in the percentage of dry holes. The average initial production of new wells was very much less than in 1917.

The outstanding feature during the year was the elevation of two districts, previously rated as of little consequence, into the rank of important producing territory. These districts were at West Columbia in Brazoria County, about 9 miles from Damon Mound, and near Hull in Liberty County. At West Columbia drilling had been carried on intermittently for 10 years or more, the earlier attempts having obtained small quantities of oil at shallow depths. Interest in the pool was revived in January by the completion of the Tyndall-Wyoming Oil Co.'s well No. 2, on the Hogg tract, which was reported to have started flowing at from 200 to 300 barrels a day for a short time. In June the Texas Co.'s No. 7 well, on the Kaiser tract, was reported

to have started flowing at 2,000 barrels a day from a depth of 2,570 feet. The largest well reported drilled during the year was brought in on December 3 by the Humble Oil & Refining Co., in block 25 on the Hogg tract. This well was reported to have started flowing at the rate of 10,000 barrels a day. At the end of the year West Columbia was firmly established as one of the important producing districts of coastal Texas.

The development of the important pool 2½ miles south of Hull in Liberty County was carried out largely by the Republic Production Co. on an 800-acre tract, the property of the Houston Oil Co. Well No. 1 near the center of this tract was reported abandoned in salt water around 1,400 feet. No. 2, 2,500 feet southeast of No. 1, was abandoned in salt water at 2,700 feet. No. 3, northeast of No. 1, was also reported abandoned in salt water at 3,700 feet but later was tested between 2,200 and 2,300 feet and developed a good producing well which was rated at 1,000 barrels a day. Well No. 4 on this tract was rated at 2,000 barrels a day.

Goose Creek and Humble, the two largest producing pools of the coastal Texas fields, continued to furnish large producing wells throughout the year. At Goose Creek a number of wells with initial capacities of 1,000 to 10,000 barrels a day were reported. The E. F. Simms No. 6 well, on the Sweet tract, was probably the largest and was rated at more than 10,000 barrels a day. The effect of these large wells at Goose Creek was to increase its production materially, making it the largest producing district of the field.

Despite the bringing in of several new wells rated at from 1,000 to 6,000 barrels initial daily capacity, the Humble pool showed a slight decrease in production for the year.

An extension of the Saratoga pool was opened up by the completion of a 3,000-barrel well by the Empire Gas & Fuel Co., at a depth of 2,045 feet, a quarter of a mile east of previous producing territory. Later two 12,000-barrel wells were reported from this eastern extension and also several failures.

Southern Texas.

Increased drilling activity was reported from Bexar and Duval counties. Near Noleda in Duval County, 90 miles south of San Antonio, a number of wells 200 to 500 feet in depth have been producing for several years.

LOUISIANA.

GENERAL STATEMENT.

Production of petroleum in Louisiana in 1918 was 16,042,600 barrels, an increase of 4,650,399 barrels, or 41 per cent, as compared with the output in 1917. Increase in production is credited almost entirely to the intensive development in the Pine Island district in Caddo Parish. The development of the prolific Pine Island pool in northern Louisiana resulted in wildcat drilling over considerable territory. Production in northern Louisiana was 13,304,399, barrels as compared with only 8,561,963 barrels in 1917. Of this total Caddo Parish contributed 11,143,890 barrels.

The average price received at the wells for all grades of petroleum produced in Louisiana in 1918 was $1.716 a barrel and the market value of the entire output was $27,535,060, a gain of 12 cents in average market price, and of $10,310,458, or 60 per cent, in gross market value, compared with 1917. The average market price of the petroleum of the northern division increased from $1.64 a barrel in 1917 to $1.73 a barrel in 1918, a net gain of 9 cents, or 5 per cent, and the market value of the output in 1918 exceeded that of the output in 1917 by $8,959,827, or about 64 per cent. The average market price of the oil produced in the coastal division increased from $1.113 a barrel in 1917 to $1.643 a barrel in 1918, a net gain of 53 cents, or 48 per cent, and the market value of the output exceeded that of the output in 1917 by $1,350,631, or 43 per cent.

DEVELOPMENT.

The increase in price of petroleum and the discovery of the rich Pine Island pool late in 1917 resulted in a marked increase in drilling activity in Louisiana, and 712 wells were drilled in 1918 primarily for petroleum, as compared with 634 in 1917. Of the total drilled in 1918, 506 were rated as oil wells with an average initial output of 410.7 barrels a day, 58 produced gas only, and 148, or 21 per cent, were dry holes. The success of operations in Louisiana was shown by the marked increase both in production and the average initial yield of new wells and also in the lower percentage of dry holes.

NORTHERN OR STRATUM DIVISION.

In northern Louisiana, which is included in the Mid-Continent field (pp. 1052–1059), 518 wells were completed in 1918, as compared with 456 completed in 1917. Of the wells drilled in 1918, 389 were rated as oil wells with an average initial yield of 439.9 barrels a day. This average initial yield was more than twice as great as the corresponding rate in 1917.

The feature of the year was the activity in the Pine Island district. This district was discovered in the spring of 1917, and development was well underway by the beginning of 1918. In September, 1918, the Old Settlers Oil Co. brought in a well which started flowing at the rate of 3,000 barrels a day on the Lynn lease, 2½ miles east of the original pool. Many good wells were completed and the field was gradually expanded until the proved productive territory at the end of the year covered an area of approximately 20 square miles. The crude oil from this well is reported to have a gravity of 26° to 32°

Baumé and to have practically no gasoline content. At the end of the year the increasing production of the Pine Island district was far in excess of the pipe-line facilities. For this reason and also because of the cessation of war activities there was a great decrease in the demand for fuel oil, which resulted in the curtailment of the quantity of oil handled by the pipe-line companies from this field.

In November, 1918, it was reported that the Texas Co. had obtained a well rated at 1,000 barrels a day in the Dolet Lobe district on the border of Red River Parish, about 3 miles south of Gusher Bend. A number of tests made in this vicinity at the time of the Crichton boom resulted in dry holes. The well drilled by the Texas Co. was drilled to a greater depth. Several wells in this district were completed before the end of 1918. In the Monroe gas field in Ouachita Parish efforts were made to develop an oil field by deep drilling, but nothing of importance was discovered.

In Claiborne Parish near Homer, the Consolidated Progressive Oil Co. completed a well in September, 1918, on the Featherstone lease, in sec. 20, T. 21 N., R. 7 W. This well was in wildcat territory and opened up a new pool. This was the important find of the year in Louisiana not only in the opening up of a new pool but in giving promise for good oil territory over a large area where oil had not previously been discovered. In Bossier Parish interest was centered chiefly in the Elm Grove district. Tests for oil in the following parishes in northern Louisiana proved unsuccessful: La Salle, Morehouse, Natchitoches, Ouachita, Union, and Webster.

SOUTHERN OR SALT-DOME DIVISION.

The production of petroleum from the oil pools in southern Louisiana in 1918 was 2,738,201 barrels, a slight decrease from the record of 1917. The market value—$4,499,328—on the other hand was $1,350,631, or 43 per cent, greater than that of the output in 1917. Decrease in production is reported from Jennings, Anse la Butte, Edgerly, and New Iberia. An increase in production was reported from Vinton and from the old Welsh district, from which the Survey was unable to obtain record of any oil produced in 1917.

Increase in drilling activity in the Gulf Coast field resulted in the completion of 194 wells in 1918, as compared with 178 in 1917. Of these wells completed 117 were rated as oil wells, with an average initial yield of 273.6 barrels per day. The percentage of dry holes—39 per cent—was less than in 1917, but the average initial yield of new oil wells was also very much less. Increase in drilling activity was reported from Anse la Butte, Jennings, and Vinton. Edgerly, Jennings, and Vinton all showed a decrease in percentage of dry holes but at the same time a decrease in the average initial yield of new wells. In the New Iberia pool developed in 1917 results were discouraging inasmuch as 8 out of the 10 new wells reported were dry holes and new production amounted to only 85 barrels. The Welsh district was not successful with 4 completions, all of which were oil wells with an average yield of 93.7 barrels.

Drilling for oil in the following parishes was unsuccessful: Allen, Calcasieu, Cameron, Evangeline, Jefferson Davis (outside of the Welsh pool), Orleans, Plaquemines, St. Martin, Terrebonne, and Vermilion.

SUMMARY OF WELLS DRILLED.

The statistics of field operations presented in the following tables are compiled from trade-journal sources and differ somewhat from those on page 990, obtained from reports received directly from the oil producers.

Wells completed in Louisiana, 1914–1918.

ROCKY MOUNTAIN OIL FIELD.

GENERAL STATEMENT.

The Rocky Mountain field embraces all areas of production of petroleum in Colorado, Wyoming, and Montana, as well as a number of areas of prospective production in Utah and New Mexico. Petroleum in this field is obtained from strata of Carboniferous and Cretaceous age, the oil occurring generally in sandstone layers, though found occasionally in limestone and rarely in fracture zones in shale. Anticlinal and dome structures are the most favored places of accumulation of oil, though areas of commercial production have been found in this field on monoclinal and terrace structures. The oils from older strata range in gravity from 18° to 24° Baumé, are of asphalt base, and are utilized chiefly for fuel; those from the Cretaceous rocks range between 32° and 48° Baumé, are of paraffin base, and are in wide demand for refining.

Statistics of production in the oil districts of Wyoming, Colorado, and Montana indicate an output in 1918 of 12,808,896 barrels, an increase of 3,609,586 barrels, or 39.24 per cent, as compared with the output in 1917. The value of the output in 1918 was $18,474,078, as compared with $11,322,248 in 1917. The average price received at the wells for all grades of Rocky Mountain oil in 1918 was $1.44 per barrel, a gain of 21 cents, or 17 per cent, over the average in 1917. The posted market price of Grass Creek-Elk Basin grade, the class which includes the greater part of the oil sold in the open market in this field, opened the market at $1.70 a barrel and advanced on March 21 to $1.85, remaining stationary at this price to the end of the year.

PETROLEUM PRODUCED.

Petroleum produced in the Rocky Mountain field in 1917 and 1918, in barrels.

COLORADO.

GENERAL STATEMENT.

The total production of oil in Colorado in 1918 was 143,286 barrels, an increase of 22,055 barrels, or 18 per cent, as compared with the output in 1917. Increase in production came from the Florence district in Fremont County, which produced in 1918 a total of 134,895 barrels, as compared with 114,664 barrels in 1917. Decrease in production is reported from the Boulder district in Boulder County. A small production is also reported from Mesa and Rio Blanco counties. The average price received for Colorado oil at the wells in 1918 was $1.315 a barrel, an average increase of 26 cents, as compared with 1917. The total value of the output in 1918 was $188,472, as compared with $128,100 in 1917.

DEVELOPMENT.

The following wildcat tests were completed in Colorado in 1918: In Adams County, the Mid-Colorado Oil & Gas Co. is reported to have abandoned its test at Aurora, 9 miles east of Denver, at 3,740 feet, after three years' work. In Washington County, in sec. 2, T. 2 N., R. 53 W., a test well was drilled by the Akron Oil & Gas Co. to a total depth of 4,200 feet; it obtained a trace of oil at 2,000 feet and a little gas at 3,800 feet. In Pueblo County, in sec. 14, T. 20 S., R. 66 W., a well, drilled by the Eureka Oil Co., was reported in September as abandoned at 1,800 feet. In Kiowa County, in sec. 36, T. 17 S., R. 49 W., a showing of oil was reported in a well drilled by the Rush Creek Oil Co.

PETROLEUM PRODUCED.

WYOMING.

GENERAL STATEMENT.

Wyoming showed a steady increase in production of crude oil in 1918, furnishing a total output of 12,596,287 barrels, an increase of 3,617,607 barrels, or 40 per cent, as compared with the output in 1917.

Converse County had the largest increase in production, 3,082,026 barrels in 1918, as compared with 665,432 barrels in 1917. Hot Springs, Natrona, and Fremont counties also showed a marked increase in production. A decrease was reported from Big Horn, Park, and Uinta counties. The average price received at the wells for Wyoming oil was $1.44 per barrel, an increase of 21 cents, or 17 per cent, as compared with the average price in 1917. The value of the total output in 1918 was $18,159,778, as compared with $11,047,876 in 1917.

DEVELOPMENT.

Records of field operations compiled from trade-journal sources and comparable to the records used in discussing field operations in other States have not been compiled by the Survey prior to 1918. These records for 1918 show total completions for the year of 250 wells, of which 158 were oil wells credited with an average initial yield of 106.45 barrels per day, 29 produced gas only, and 63, or 25 per cent, were dry holes.

Natrona County continued as the leading producer of oil in Wyoming in 1918 and furnished 42 per cent of the total output of the State for the year. The Salt Creek field continued to furnish new wells of large capacity, the best of which was the well of the Mid West Refining Co., in sec. 25, T. 40 N., R. 79 W., which was brought in late in September and is reported to have started flowing 8,000 to 10,000 barrels a day. Production was reported from the so-called "Lower Wall Creek sand." A total of 63 wells were reported drilled in Natrona County during the year, of which 28 were oil wells, credited with an average initial yield of 312.5 barrels a day.

The marked increase in production in Converse County was due to the rapid development during the year of the Big Muddy district. A total of 55 wells were drilled in this county during the year, of which 47 started producing at the rate of 160.3 barrels a day.

The most important discovery of the year was that of the Lance Creek field in Niobrara County. A discovery well in the Lance Creek field in sec. 36, T. 36 N., R. 65 W., was brought in at a depth of 665 feet by the Ohio Oil Co., on October 6, 1918. At that time the yield of the well was estimated at 1,200 barrels a day. Some small wells had been completed in the same general district at shallower depths earlier in the year, but the discovery of the deep sand marked the opening of an important field.

The oil from the deep sand is low in sulphur and the highest specific gravity contains from 45 to 50 per cent gasoline. Another important discovery was made by the Ohio Oil Co. on the Rock Creek dome in Carbon County in the spring of 1918. The most interesting disappointment during the year in development work in Wyoming was the striking of a large salt-water well on the Tisdale dome to the west of the Salt Creek field. This structure during the past few years has been looked upon as one of the best prospects for oil in Wyoming.

Near the Lost Soldier field the Producers & Refiners Corp. found a very productive spot on the Ferris dome where a 500-barrel well was obtained at a depth of 1,536 feet. In the Big Horn Basin interest was centered in the early part of the year on the Warm Springs anticline east of Thermopolis, where a number of good wells were reported.

Dry holes were reported on the Duncan dome, 25 miles southwest of Thermopolis, and in the Lucerne dome, 65 miles south of Thermopolis. A large salt-water well was reported from the Murphy dome in Hot Springs County.

PETROLEUM PRODUCED.

Petroleum produced in Wyoming in 1917 and 1918, by counties, in barrels.

MONTANA.

GENERAL STATEMENT.

The quantity of petroleum marketed from wells in 1918 was 69,323 barrels, a decrease of 30,076 barrels, or 30 per cent, as compared with the output in 1917. The entire production came from wells in Carbon County, in the north end of the Elk Basin district.

DEVELOPMENT.

Prospecting work for petroleum fields in Montana in 1918 was practically at a standstill. A few wells in widely separated localities were completed during the year, but none of these localities showed promise of developing into an oil field. In Cascade County, at Sun River, 60 miles west of Great Falls, a gas well was drilled early in the year with a capacity of 50,000 cubic feet. Some gas wells were also developed in Sweet Grass County, about 70 miles north of Great Falls. A well drilled by the Montana Yellowstone Oil Co. in sec. 4, T. 14 N., R. 55 E., Dawson County, was reported in August to have reached a depth of 4,000 feet.

CALIFORNIA.

By Walter A. English.

GENERAL STATEMENT.

The year 1918 saw a substantial increase in California in the production of crude petroleum from 93,000,000 to more than 97,000,000 barrels. Since 1913, when a production of 97,000,000 barrels was reached, the quantity annually produced has varied between 90,000,000 and 100,000,000 barrels, except in 1915, when it fell to 86,000,000 barrels. This rather uniform production has prevailed during a series of years which have seen much greater changes in the production of the principal eastern fields.

The increase in quantity of oil produced in 1918 was accompanied by a slight change to an average of slightly higher gravity, largely because of the increasing importance of the southern California fields. A new grade of oil for this State has also come on the market, the Ventura County paraffin-base oil, from which various paraffin products are now being manufactured in the refinery at Santa Paula.

The average price for the year was $1.21 a barrel, this being the first year since 1894 that crude oil has averaged over $1 a barrel at the well. As production in volume in California did not begin until

about the year 1900, it may be said that this is the first appearance of "dollar oil" in the history of the State. Price changes during the year were upward, the base price quoted by the Standard Oil Co. being raised on May 1 from $0.98 to $1.23 a barrel. Present conditions in the industry promise an indefinite continuation of this upward tendency of prices unless checked by large imports of foreign fuel oil. The tendency to give a greater differential for high gravity oil was continued in 1918. This is a natural result of the increasing demand of oil for refining as opposed to the demand for fuel oil.

That the stimulation of high prices to greater production was not greater is due chiefly to two factors. The first factor is the increased cost of all labor and of materials used in the oil industry. The 8-hour day and increased wages, together with the unprecedented cost of all steel equipment, have absorbed into the cost of production much of the increased price received for the oil. The other factor is the decrease in extent of territory favorable for wildcatting and the gradual drilling up of the proved territory. California has already maintained her peak production for six years and will probably continue to do so for several years more, a feat not duplicated by any of the older fields of the country. As a field becomes older it naturally becomes less responsive to the stimulation of high prices.

As in 1917 the total consumption outstripped production with a resulting lowering of stocks during 1918 to the extent of about 500,000 barrels.

The year saw general strengthening of larger companies at the expense of small ones. The established companies were able almost to exclude new organizations from drilling the expensive tests in deep wildcat territory in southern California. The larger companies have a large proportion of the good land in the newly developed Montebello field.

Many of the important properties in the Midway district continued to be operated by a receiver as a result of the legal controversy over the withdrawals of land by the United States in 1909 and 1910. A few claims were allowed to go to patent after investigation by the Interior Department, but the majority are still held up pending action by Congress. The most important legal decision of the year was in the Elk Hills land case, which was decided by the United States circuit court of appeals in favor of the Southern Pacific Co. The case was appealed by the Government to the United States Supreme Court. If this decision is not reversed it probably means that the title of the railroads to all oil lands received in grants in the State is valid.

During the year electric motors were tried out at several places for drilling wells. Two wildcat wells of the Shell Co., southwest of Puente were equipped with motors, as was the Buick well near the San Fernando tunnel. Several wells in the Santa Paula field were drilled by motors. From all accounts it appears that this type of power is fairly satisfactory and sufficiently flexible, though requiring slightly different methods of manipulation by the driller. An innovation was the use by the Brea Canyon Oil Co. of oil as a drilling fluid in one of its wells. It was claimed that the use of oil instead of water reduced the tendency of the casing to freeze.

DEVELOPMENT.

VALLEY FIELDS.

In 1918 only 491 oil wells were completed in the Valley fields, as against 563 in 1917. As a result, the total production for these fields dropped from 69,000,000 to 65,000,000 barrels. The falling off in new wells and in production was particularly marked in the Midway-Sunset field which fell off nearly 10 per cent in monthly production between the first and the last months of the year. Until land now in litigation is open to active development, this, the largest field in the State, seems due for a slow decline from year to year.

Coalinga.—Drilling activity continued in the Coalinga field at about the same rate as in 1917, and was confined almost entirely to proved territory. The Shell Co., operating in the east-side field, was particularly active. This company successfully used the mudding process to shut off water in some of its wells. Water troubles, which at one time seriously threatened the west side, seem to have been successfully averted. The Crescent wildcat well at the south end of the Kettleman Hills was abandoned as dry at 3,500 feet. The Southern Pacific Co. has begun a wildcat test in the Parkfield district, 20 miles southwest of Coalinga.

Lost Hills.—The number of completed oil wells in the Lost Hills dropped from 72 to 23, as compared with the previous years, with a resultant drop in production from 4,000,000 to 3,600,000 barrels. The development in 1917 was exceedingly rapid, the size of the field considered, and it was to be expected that this rate could not be kept up indefinitely. No new territory was proved during 1918 and the development of the half-proved north extension of the field was disappointing.

Belridge.—As in the Lost Hills district, 1918 saw a falling off in development in Belridge. Several wells were drilled to the shallow sand, but these did not offset the natural decline of the older wells. No new territory was proved.

McKittrick.—The combined production of McKittrick and Belridge was 4,815,610 barrels, of which about two-thirds came from the old McKittrick field. The latter is one of the oldest fields in the State, and though almost completely drilled up its wells are holding out very well, even though a decline in production from year to year is now inevitable.

The Standard Oil Co. continued its deep drilling on the "front," and though "shows" and small short flows were obtained, the water conditions have not been mastered thus far. A large gas well was struck by the Doheny-Pacific Petroleum Co. in sec. 2 (31–32) south of McKittrick.

Midway.—The new production of the 153 wells completed during 1918 in this field was insufficient to offset the loss due to decline and abandonment of older wells, the annual marketed production falling from 28,829,674 barrels in 1917 to 26,407,728 barrels in 1918.

The Southern Pacific, Standard, and Santa Fe were the most active developing companies, the latter two, desiring fuel oil, paid particular attention to the low gravity territory. Toward the end of the year a slight slackening in demand for fuel oil caused a decline from the most active development. No big gushers were brought in during

the year. A thousand-barrel well is now considered a big well, and the field average for all wells has fallen to below 50 barrels per well. Nevertheless the field still retains its place as the largest single field in California, and probably has the largest reserve of oil in any field in the United States.

Sunset.—The year 1918 saw an increase in drilling activity, as compared with 1917, with 82 completions as against 64. This increase in wells was, however, not sufficient to offset the natural decline of wells previously drilled, and a falling off of nearly 10 per cent in production took place. Water conditions in this field have proved among the most difficult to combat, owing to the close association of oil and water sands. Despite this handicap substantial progress has been made in correcting and preventing water trouble. The year failed to see the completion of any of the prolific and spectacular gushers which made the Maricopa Flat famous a few years ago. Wells of over a thousand barrels of initial flow are still obtained occasionally, but the flush gusher production of the big wells is a thing of the past, even though the field is far from completely developed.

Kern River.—The output of Kern River during 1918 of 7,500,237 barrels represents a decline of nearly 8 per cent from the 8,144,348 barrels produced in 1917, and less than half the maximum annual production. The rate of decline for 1918 from 1917 was 7.91 per cent, although the decline in 1916–17 was only 1 per cent. This increased rate of decline represents a resumption of the normal decline which was broken by the active campaign of 1917 to repair old wells and get more oil by better methods of production. As these changes are completed the old rate of decline once again asserts itself. Despite the "old age" status of the proved field, Kern River may one day come to life with another boom because of extensions to the northwest. The Standard Oil Co., of California, has been drilling in this region for several years and has produced oil from several wells, but has thus far failed to complete a steady producer. In September it started well No. 5 on sec. 21 (28, 27), despite the fact that previous wells have not yet become commercial producers, thus indicating the faith of this company in the ultimate success of operations in the Kern River front. The Hale syndicate is also drilling north of Kern River near McFarland, and the Visalia-Midway to the south of Edison.

COASTAL DIVISION.

The number of new wells completed in the coastal division was 79, as compared with 52 in 1917. The greater part of these were drilled in the course of the rapid development of the new Casmalia field, and of the South Mountain field in Ventura County. The increase in annual production from 5,910,238 barrels to 6,848,904 barrels, as compared with 1917, was also largely because of the increase brought about by new wells in the above-mentioned fields.

Santa Clara County.—During the year some of the old wells in Moody's Gulch were cleaned out, and what might be termed a rejuvenated flush production of a few barrels per day of very light oil was obtained. At the Sargent field a deep test failed to disclose anything worth while.

San Luis Obispo County.—The Tiber Oil Co., in the Edna district, increased its production to some 4,000 barrels a month. This district accounts for most of the combined Santa Clara and San Luis Obispo production.

Santa Barbara County.—The 11.94 per cent increase in marketed oil over the previous year is largely a result of continued active drilling in the Casmalia district. The Associated Co., desiring a large production of this grade of oil, had as many as eight drilling outfits working on their property. The Doheny-Pacific Petroleum Co., in the same field, installed a cracking plant which, unlike most cracking plants, was not designed primarily to produce greater quantities of light distillates but to reduce the viscosity of the heavy oil so that it could be pumped through pipe lines without excessive heating. The old Santa Maria field saw only a small amount of development, and in the Cat Canyon and Lompoc districts there was very little new work.

Tests northwest of Los Alamos have on the whole been disappointing, a number of deep holes yielding only a small output of oil. During the year the Standard Oil Co. of California finished its fifth deep test in the Santa Maria district, all of them dry holes, and it has, for the present at least, given up operations in this region.

Ventura County.—The outstanding feature of the year was the development in the South Mountain field directly south of Santa Paula. It was largely because of this development that the oil marketed increased 37.94 per cent over 1917. Although the productive area in this new field will not likely be very large, the high quality paraffin-base oil obtained makes this field a valuable addition to the California resources.

During the year the various companies continued efforts to shut off water in the light-oil field in Ventura Canyon. An oil of lesser gravity was also struck half a mile to the west of the wells producing the 54° gravity oil.

In the Simi district the Doheny-Pacific Petroleum Co. continued to develop shallow wells good for 20 to 100 barrels of 34° oil initial production, and at the end of the year it had five wells in process of drilling.

Wildcat tests were started 6 miles north of Camarillo and 5 miles northeast of Somis.

SOUTHERN DIVISION.

Largely as a consequence of the rapid development of the Montebello field and the continued increase in the production of the Standard Murphy Coyote property, the southern California district increased in oil marketed and in relative importance as compared with the San Joaquin Valley fields. Indeed at the end of the year the Whittier-Fullerton district was only slightly behind the famous Midway-Sunset field in daily production, and judged by the amount of new drilling going on the southern field may be the foremost single field of the State by the end of another year.

During the year 106 oil wells were completed in southern California as against 70 in 1917, which gives an index to the remarkable increase in activity. At the end of the year 108 wells were being drilled in this district. The Coyote Hills and Montebello have been the most important fields in respect to amount of recent drilling, quantity

of production, and increase in production. It was because of the increase over 1917 of more than 11,000,000 barrels in oil marketed from these two fields that California showed an increase instead of a decrease in production in 1918.

Los Angeles City and Salt Lake.—The Los Angeles City field is a distinctly old-age field, in which no new drilling took place. Because of scarcity of oil there was some talk of removing some of the city's restrictions against new operations in this field as a war measure. A few old abandoned wells were cleaned out and maintained a profitable production for a short time thereafter. Development was also practically at a standstill in the Salt Lake field, with only one new well during the year and a decline of 6.05 per cent in annual production.

Montebello.—Although only discovered in 1917 a very rapid development took place in the Montebello field during 1918, which brought the output up to 6,532,745 barrels for the year, an increase of 687.6 per cent over the output in 1917. Such activity was a natural outcome of the war demand for oil and the high initial production of wells in this field, which averaged more than 1,000 barrels initial production. Development has been so rapid that already the limits of proved territory are pretty well defined and the field will probably reach its peak of production within the next year or two.

Newhall.—During the year the Tunnel Petroleum Co. has brought in some small wells north of the old Ellsmere field, and the Buick Oil Co. has been drilling a wildcat well on the divide east of the Fernando tunnel.

Whittier-Fullerton.—Within this district, which comprises the most important fields of southern California (except Montebello), there was an increase in production of 1,036,683 barrels. This increase amounting to 6 per cent over the output of 1917, was made possible largely by the rapid development and splendid production obtained in the Coyote Hills, and particularly on the Standard Murphy property. Wells on this property, although over 4,000 feet deep, are now completed in a comparatively short time and with such satisfactory drilling methods that this field is one of those least affected by water. On the other hand the Union Oil Co. has just completed its fifth year of work on its Bastanchury lease adjacent to the Standard Murphy, and has spent a large amount of money without getting a successful well. This, despite the fact that oil is known to be present and several short flows of considerable volume were obtained from its deep tests. The difficulty has been largely to locate water and oil sands accurately and to shut off water successfully at a depth of over 4,500 feet. In the East Coyote Hills the Union has drilled several wells on its properties but has not done any great amount of development, apparently preferring to exploit shallower territory during the present pressure for oil.

The most active development in the old Whittier field has been on the Standard Murphy Whittier property, where this company has been active both in redrilling and on new wells.

In Brea Canyon the Birch, Fullerton, and Columbia Oil companies each completed a well during the year. These wells are all about 4,000 feet deep and were among the hardest and most expensive in the State to drill, but when completed are good for several hundred barrels initial production and are remarkably long-lived.

In the Olinda field most of the new drilling was in the southernmost part of the field on the Union Naranjal and Stearns leases and on the West Coast Oil Co.'s lease.

MISCELLANEOUS WILDCAT TESTS.

LOS ANGELES COUNTY.

Whittier-Fullerton district.—Many tests in wildcat territory were made in this district, but the only successful one of the year was the Standard Kraemer No. 1 east, at Yorba Linda. This well came in in September at initial production of 200 to 350 barrels. Interest was immediately aroused in this district and all adjacent lands were leased and half a dozen other test wells were started before the end of the year. The geologic structure indicates that the field will be narrow and probably of only small areal extent.

The Mascot Oil Co. had a well drilling across the river east from Montebello field and a well on Rideau Heights a little to the south, both these wells being on the extreme west end of Whittier Hills. North of this is the Union Oil Co.'s El Monte, wildcat, and two wildcat wells of the Shell Co. are farther east between Montebello and the town of Puente. No conclusive results were obtained at any of these wells during the year.

The Copa d'Oro well, 3 miles north of the Brea Canyon field, was abandoned at a depth of nearly 4,000 feet. A show of oil was reported at 3,690 feet. About a mile farther north is the Currier well, also abandoned during the year after six years spent in drilling to a depth of about 4,000 feet. The Sentous test well of the Petroleum Development Co. (Santa Fe) northwest of Puente, was abandoned at 3,955 feet. A rig was erected toward the end of the year for a test in the Chino Hills south of Pomona. The Myers well of the Union Oil Co. east of Santa Fe Springs continued drilling below 4,300 feet. The Union Chapman well, about a mile northwest of Richfield, was drilling throughout the year and encountering much hard formation.

Near Los Angeles were several tests which were abandoned or had not struck oil during the year. The Mount Washington well, northwest of Los Angeles, continued drilling intermittently, below 2,000 feet.

East of Los Angeles was the Amalgamated Oil Co.'s Huntington well, in Boyle Heights, which got salt water at 3,030 feet and went to over 4,000 feet before being abandoned. The Jordan well, east of Eastlake Park, also failed to get any oil during the year but is still drilling.

Between Los Angeles and the sea three wells were abandoned and another test was started. The Union Bixby well, north of Long Beach, was abandoned early in the year because of mechanical trouble and poor outlook. The Highland Development Co.'s well near Dominguez was abandoned after prolonged efforts to shut off water and bring it in as a gas well, an upper gas sand having been encountered. The Bartolo Oil Co. abandoned its test southwest of Los Angeles, though the Standard Oil Co. started a well near by on its Baldwin lease, and was down to 2,500 feet by the end of the year.

In the San Fernando Valley the Luetge well, near Burbank, was abandoned at 1,800 feet. Farther west, southwest of San Fernando, the Standard Oil Co. started a test on the Sunshine ranch.

ORANGE COUNTY.

Near Newport efforts were continued to develop a field and the Liberty Petroleum Co. brought in a well rated at as high as 150 barrels initial, of 12° Baumé oil at a depth of about 2,000 feet. The production soon fell off and water trouble as well as the viscosity of the oil made the well of doubtful value. Steam was used to heat the oil in the well in order to pump it. On the Irvine ranch, southwest of Santa Ana, the Standard Oil Co. started a test well which had reached a depth of about 3,500 feet by the end of the year.

SAN DIEGO COUNTY.

The test well of the Balboa Oil Co., near the city of San Diego, was abandoned at 5,700 feet. This is the deepest well in the State.

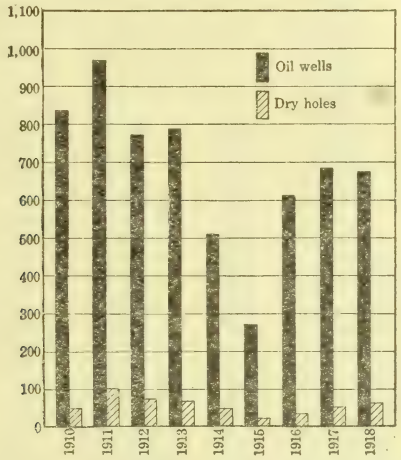

FIGURE 109.—Comparison of number of producing oil wells with dry holes drilled in California, 1910–1918.

OUTPUT OF REFINERIES.

The Bureau of Mines has published the following tables showing the essential statistics concerning the refining of crude oil in the United States in 1918.

Detail of oils run to refinery stills in 1918.

1918	Crude oil (barrels).	Other oils.				Total oils run (barrels).
		Purchased and rerun (barrels).	Own oils rerun (barrels).	Casing-head gasoline (barrels).	Total other oils (barrels).	
January	23,842,587	1,591,111	531,909	177,314	2,300,334	26,142,921
February	23,386,676	1,631,065	457,325	209,943	2,298,333	25,685,009
March	26,239,662	2,674,985	783,925	237,962	3,696,872	29,936,534
April	26,201,544	2,268,908	479,050	208,286	3,956,244	30,157,788
May	28,510,698	3,347,807	567,316	196,900	4,112,023	32,622,721
June	28,140,479	2,701,865	621,449	159,956	3,483,270	31,623,749
July	29,170,718	3,304,145	2,430,269	217,123	5,951,537	35,122,255
August	28,534,275	3,566,207	2,544,956	265,190	6,376,353	34,910,628
September	28,390,431	2,610,151	2,724,271	151,325	5,485,747	33,876,178
October	29,237,767	2,216,073	3,189,018	166,756	5,571,847	34,809,614
November	27,411,636	2,690,391	1,540,117	227,246	3,857,754	31,269,390
December	26,958,157	1,579,967	1,661,586	233,337	3,474,890	30,433,047

[a] Figures on exports are taken from reports of the Bureau of Foreign and Domestic Commerce.
[b] Includes fuel or bunker oil for vessels engaged in foreign trade, 6,578,141 barrels.

IMPORTS.[1]

Despite the fact that the United States is the world's principal producer and distributor of petroleum and petroleum products, its import trade in those commodities is steadily increasing. This is especially true with regard to grades of oil desired for use as fuel, including both crude petroleum and "topped crude," from Mexico.

Petroleum, paraffin oil, and ozokerite and paraffin wax imported for consumption in the United States, 1914–1918.

Year.	Crude petroleum.		Paraffin.		Ozokerite and paraffin wax.		Total value.
	Quantity (barrels).	Value.	Quantity (barrels).	Value.	Quantity (pounds).	Value.	
1914	17,247,483	$11,465,466	2,481	$36,687	15,516,242	$824,234	$12,326,387
1915	18,140,110	10,389,012	1,707	85,121	10,259,445	553,397	11,027,530
1916	20,570,075	12,602,811	902	75,925	12,266,191	706,874	13,385,610
1917	30,162,583	16,400,017	93	3,514	10,608,099	729,210	17,132,741

PRICES.

The following tables, compiled from weekly quotations in the Oil, Paint, and Drug Reporter (New York), show the fluctuations in export price of the principal kinds of illuminating oil and of gasoline entering the foreign trade and, for comparison, the wholesale price of the same products to domestic jobbers in New York. The quotations on illuminating oil are for 150° F. fire test, water-white kerosene, and on gasoline for 68° to 72° Baumé auto naphtha. Quotations on standard white kerosene ranged 1 cent lower in price than quotations on the water-white grade.

FUEL OIL.

GENERAL STATEMENT.

Complete statistics of fuel oil are not available. Data compiled by the Bureau of Mines show that 174,318,989 barrels of fuel oil and gas oil were produced by refiners of crude petroleum in the United States in 1918 and that refinery stocks of those products increased 1,931,006 barrels during the year. Reports of pipe-line and producing companies show that 43,241,316 barrels of crude petroleum were delivered for use as fuel. Records of the Bureau of Foreign and Domestic Commerce show that 37,735,641 barrels of petroleum, the greater part of which was used for fuel, was imported, chiefly from Mexico, in 1918 and that 33,495,806 barrels of crude oil, gas oil, fuel oil, and residuum were exported from the United States in the same period.

The fuel oil utilized in the United States consists in greater part of topped or semirefined petroleum of asphlatic or semiasphaltic base, though limited quantities of low-grade crude petroleum of asphaltic base and of the refining residuals of petroleum of paraffin base are also used. Because of the development of successful methods of refining by which ever-increasing proportions of the lower-grade products of petroleum distillation are converted into gasoline and motor fuel, the tendency in recent years has been decidedly away from the use of petroleum in the crude state as fuel, and to-day only the grades of crude oil averaging in gravity below 20° Baumé are considered as being available for use as fuel, without some form of refining. Outside of California, where some 35 to 40 per cent of the annual output of crude oil is of a gravity below 20° Baumé, the requirements of fuel oil in the United States are satisfied, except locally, by the product of the topping plants and petroleum refineries and by imports of low-gravity crude oil or of topped crude from Mexico.

RAILROADS.

Reports submitted by railroad companies that operated oil-burning locomotives in the United States show that the quantity of fuel oil consumed by them in 1918 was 36,713,667 barrels, a decrease of 5,524,898 barrels or about 10 per cent of that so consumed in 1917.

Fuel oil consumed by the railroads of the United States, 1909–1918.

Oregon-Washington Railroad & Navigation Co.
Spokane, Portland & Seattle Railway Co.
Washington, Idaho & Montana Railway Co.
Wyoming:
Chicago, Burlington & Quincy Railroad Co.
Chicago & Northwestern Railway Co.

UNITED STATES NAVY.

The greatly increased use of fuel oil by the Navy is shown by the following statistics furnished by the Navy Department:

Consumption of fuel oil by the United States Navy.

	Barrels.
Fiscal year ending June 30, 1919	5,530,932
Fiscal year ending June 30, 1918	4,994,367
Fiscal year ending June 30, 1917	2,079,580

FIELD USE.

The quantity of crude oil consumed during 1917 and 1918 on producing properties, chiefly in the California and Gulf coast fields, as fuel for drilling and pumping is shown in the following table. The statistics, compiled from reports of producing companies, show that 1.4 per cent of the total petroleum output of the United States in 1918 was thus consumed.

Crude petroleum used as field fuel in 1917 and 1918, in barrels.

Field.	1917	1918
Appalachian		6,681
Lima-Indiana		570
Illinois	3,287	4,300
Mid-Continent	462,136	1,086,469
Gulf	1,577,159	1,979,826
Rocky Mountain	16,551	107,590
California	2,798,225	2,505,052
	4,857,358	5,690,488

PRICES.

The average price of fuel oil in 1918 continued the advance of 1917 until about the middle of the year, when the increase was halted by the stabilization program of the Fuel Administration. After the signing of the armistice in November, 1918, there was a distinct drop in the average price of fuel oil.

The following tabulation of monthly prices for semirefined fuel oil at various marketing centers throughout the United States has been compiled mainly from the files of the Oil Trade Journal (New York).

Monthly prices of semirefined fuel oil in 1917 and 1918.

December	1.75	1.75– 1.90	1.75	1.60	.08½– .09	.08½– .09

NOTE.—Fuel-oil quotations, especially those covering Pennsylvania points and New York, are nominal. Some spot prices were quoted slightly above the figures given. Such prices are usually small sales, whereas contract prices range under the nominal quotations. In the case of Gulf and Pacific coast fuel oil the business is almost entirely on contract.

WORLD'S PRODUCTION OF PETROLEUM.

World's production of crude petroleum in 1918 and since 1857, by countries.

Country.	Production, 1918.			Total production, 1857-1918.		
	Barrels of 42 gallons.	Metric tons.	Percentage of total.	Barrels of 42 gallons.	Metric tons.	Percentage of total.

FOREIGN OIL FIELDS.

NORTH AMERICA.

CANADA.

GENERAL STATEMENT.

The following notes on the petroleum industry in Canada are taken from the preliminary report of the Mineral Production of Canada during the calendar year 1918, Mines Branch, Canada Department of Mines, published on February 27, 1919:

The past two years have witnessed slight increases in petroleum production in Ontario due to the development of the new Mosa field in the county of Middlesex, so that the production in 1918 was not only 90,909 barrels, or 42 per cent, in excess of that of 1917, but was the largest production that has been reached since 1910. A bounty of 1½ cents per gallon is paid on the marketed production of crude oil from Canadian oil fields, the administration of the "Petroleum Bounty Act" being under the Department of Trade and Commerce. According to the bounty record the production in 1918 in Ontario was 288,692 barrels (10,104,220 imperial gallons), which at the average price per barrel of $2.70½ was worth $780,912. The New Brunswick production according to bounty payments was 3,009 barrels, worth about $7,402, or an average value of $2.46. For five years there has been a small but growing production of crude petroleum in Alberta, the greater part of which, however, does not earn the bounty because of its lightness or low specific gravity. The approximate production in 1918 was 13,040 barrels, valued at $78,240.

The total production in Canada from all sources was therefore 304,741 barrels (10,665,935 imperial gallons), valued at $866,554, as against 213,832 barrels (7,484,120 imperial gallons), valued at $542,239, in 1917.

The price of crude oil at Petrolia was quoted at $2.48 from August 20, 1917, to February 12, 1918, when the price was increased 10 cents to $2.58. On March 21, the price was again increased by 10 cents to $2.68 and, on July 10, to $2.78, remaining at this price to the end of the year. The average monthly price for the year was thus $2.69⅓, as against an average of $2.33¼ in 1917, $1.98 in 1916, and $1.39½ in 1915.

The production in barrels of the various fields in the Province of Ontario, as kindly furnished by the supervisor of petroleum bounties at Petrolia, was as follows: Petrolia and Enniskillen, 65,467; Oil Springs, 44,671; Moore Township, 6,367; Sarnia Township, 3,438; Plympton Township, 412; Bothwell, 29,116; Tilbury, 25,228; Dutton, 1,875; Onondaga, 1,186; Belle River, 447; Mosa Township, 108,988; Thamesville, 1,566.

In Alberta the production reported was obtained from 5 wells situated in the Turner Valley field, near Black Diamond, about 35 miles southwest of Calgary.

Complete returns of the production of oil refineries have not yet been received, but according to inspection returns of the Inland Revenue Department the total quantity of illuminating oils inspected during the calendar year 1918 was 55,443,056 gallons and the quantity of naphtha or gasoline and other light oils was 74,310,352 gallons.

In 1917 nine oil refineries in Canada used 199,256,799 gallons of crude oil, of which 190,882,740 gallons were imported and 8,434,059 gallons were obtained from Canadian wells. The production of refined oils and petroleum products included gasoline and motor oils, benzoline, benzine, and other light oils, 54,114,786 gallons; illuminating oils, 49,114,564 gallons; lubricating oils, 14,332,549 gallons; gas and fuel oils and tar, 55,643,707 gallons; wax and candles, 13,517,627 pounds, with asphalt and other products. The total value of the products of refineries was $25,137,143.

Exports of petroleum entered as crude mineral oil in 1918 were 270,302 gallons, valued at $28,415, and of refined oil, 1,946,967 gallons, valued at $206,675. There was also an export of naphtha and gasoline of 91,229 gallons, valued at $28,778. The exports in 1917 were: Crude oil, 2,130 gallons, valued at $183; refined oil 28,212 gallons, valued at $6,558; naphtha and gasoline 24,304 gallons, valued at $7,419.

The total value of the imports of petroleum and petroleum products in 1918 was $30,649,580, as against a value of $22,957,688 in 1917 and a value of $14,705,323 in 1916.

The total quantity of petroleum oils, crude and refined, imported in 1918 was 420,728,933 gallons, as compared with 379,148,006 gallons in 1917. A detailed record of the various classes of imports will be found in the accompanying table.

Imports of petroleum and petroleum products into Canada during the calendar years 1917 and 1918.

	1917		1918	
	Quantity.	Value.	Quantity.	Value.
(*a*) (1) Crude petroleum, in its natural state .7900 specific gravity or heavier at 60 degrees temperature, when imported by oil refineries to be refined in their own factories	*Gallons.* 183,105,102	$8,411,730	*Gallons.* 148,537,043	$8,255,387
(2) Petroleum (not including crude petroleum imported to be refined, or illuminating or lubricating oils) .8235 specific gravity or heavier at 60 degrees temperature	142,524,473	5,958,930	229,010,561	13,359,646
(*b*) Crude petroleum, gas oils (other than benzine, naphtha, and gasoline)	854,778	65,404	65,845	7,584

	.....	22,957,688	.....	30,649,580

Some further information concerning the development of the industry in Canada is taken from the year book of the Oil, Paint, and Drug Reporter.

DEVELOPMENT.

Ontario.—Drilling in Ontario has been pretty well limited to two fields of operation. On the one hand, there has been the rapid and steady development of the new shallow oil field in Mosa Township, Middlesex County. Here a lot of shallow drilling has been done, oil being encountered at between 260 and 465 feet depth. Failures have been comparatively few, since the field was pretty well defined last year; and the initial production of individual wells ranges from 10-barrel pumpers to as high as 200 barrels.

On the other hand, there has been a fairly determined effort to develop a production of oil or gas from the Trenton limestone. The most important deep tests have been those in Dover Township, but Trenton drilling has been scattered over most of the counties of southwestern Ontario. The result so far has been rather unsatisfactory, though the Dover drilling seems to be gradually proving up a small area of deep oil production.

New Brunswick.—Work in the New Brunswick fields has been largely along the line of deepening existing gas wells, with a view to securing additional production from a lower formation. This work has been limited to three or four wells and has been only moderately successful.

Alberta.—The Peace River district has seen considerable drilling in 1918, covering an extensive area, but is not yet a producing field. The production figures given are mere estimates, contingent upon the wells escaping or overcoming water troubles, such as compelled the abandonment of McArthur No. 1 well. The following summary covers the actual operations to the end of 1918:

Wells drilled in Alberta and elsewhere in Canada in 1918.

Company.	Location.	Status.
ALBERTA—PEACE RIVER DISTRICT:		
McArthur, No. 1	Sec. 31-85-20-5	Finished, abandoned.
McArthur, No. 2	Sec. 24-85-21-5	30 barrels.
McArthur, No. 3	Sec. 4-85-21-5	Drilling at 200 feet.
Victory Oil Co	Opposite Peace River	Drilling at 400 feet.
Northern Pacific	Sec. 11-85-21-5	Drilling at 800 feet.
Slipper Syndicate	High Prairie	Drilling.
Tar Island Co	Sec. 24-85-21-5	50 barrels.
Consolidated Co	River Lot 9	Drilling at 880 feet.
Community Oils	10 miles downstream	Drilling.
Three Creeks Co	Sec. 12-85-21-5	Some production.
ALBERTA—MISCELLANEOUS:		
Canadian Western Gas Co	Barnwell	Gasser, 4,000,000 cubic feet.
Northern Alberta Gas Co	Viking, No. 9	Gasser, 4,500,000 cubic feet.
BRITISH COLUMBIA:		
Spartan Oil Co	Burnaby district	Drilling at 1,000 feet.
Crows Nest Oil Co	Flathead district	Drilling at 1,580 feet.
Empire Gas Co	Aldegrove	Shut down.

PRODUCTION.

Petroleum produced in Canada, 1909–1918.

[Reported by Canada Department of Mines.]

Year.	Quantity (barrels).[a]	Value.	Average price per barrel.
1909	420,755	$559,604	$1.330
1910	315,895	388,550	1.230
1911	291,096	357,073	1.227
1912	243,336	345,050	1.418
1913	228,080	406,439	1.782
1914	214,805	343,124	1.590
1915	215,464	300,572	1.392
1916	198,123	392,284	1.979
1917	213,832	542,239	2.536
1918	304,741	866,554	2.844

[a] Barrels of 35 imperial gallons. The Canadian barrel of 35 imperial gallons is the practical equivalent of the United States barrel of 42 gallons, the difference being less than 0.03 per cent.

Petroleum produced in Canada, 1914–1918, by districts, in barrels.

District.	1914	1915	1916	1917	1918

MEXICO.

GENERAL STATEMENT.

The following quotation is taken from an official report from J. Vásquez Schiaffino, chief of the petroleum bureau of the Department of Industry, Commerce, and Labor in Mexico City, published in the Oil Trade Journal, of May, 1919:

Production by zones.—Mexico's production of crude petroleum in 1918 was 63,828,327 barrels, compared with 55,292,770 barrels in 1917, an increase of 8,535,557 barrels, or 15.43 per cent. Production in 1916 was 39,817,402 barrels.

Of the total 1918 production, 43,970,644 barrels, or the major portion, came from the Tuxpam zone, embracing what are known as the Southern districts in the State of Vera Cruz, and including among others Potrero del Llano, Juan Casiano, Cerro Azul, Los Naranjos, the Tepetate, and the Alamo. This zone produced 34,766,964 barrels in 1917.

The Tampico zone, taking in Panuco and Topila, produced 19,857,361 barrels in 1918, against 20,502,250 barrels in 1917. In the 1917 record is included the Huasteca Petroleum Co.'s Juan Casiano, Cerro Azul, and Chinampa output during the first three months, after which the production of the wells in these districts was carried into the record of the Tuxpam zone.

The Minatitlan zone produced only 321 barrels in 1918, against 23,556 barrels in 1917.

During the first six months of the year, Mexico's crude oil production was 27,933,189 barrels, while during the second half of the year it was 35,895,137 barrels.

Mexican Petroleum and Mexican Eagle.—The Mexican Petroleum Co. (Ltd.), (Pan American Petroleum & Transport Co.) and the Mexican Eagle Oil Co. (Ltd.) maintained their pronounced leadership over the other producing companies during 1918, although the latter showed a slight decrease in production as compared with its 1917 record. The Huasteca Petroleum Co. (Mexican Petroleum Co. (Ltd.), of Delaware) produced 20,186,459 barrels in 1918, compared with 17,325,171 barrels. Its allied company, the Mexican Petroleum Co. of California, produced 1,445,977 barrels, against 1,125,702 barrels. The total for the two in 1918 was 21,632,436 barrels, against 18,450,873 barrels in 1917. These are the Doheny organizations.

The Mexican Eagle Oil Co. (Ltd.) (El Águila), of which Lord Cowdray is the head and in which the Royal Dutch-Shell has purchased a large interest, produced 16,910,646 barrels in 1918, compared with 16,922,323 barrels in 1917.

The record for 1918 shows several new companies with substantial production, among them being the Cía. Mexicana de Petróleo La Libertad (Island Oil & Transport Corporation) and the Cortez Oil Corporation (Port Lobos Petroleum Corporation). The companies producing more than 500,000 barrels, in their proper order, were the Penn Mex Fuel Co., 6,854,081 barrels in 1918, against 4,129,297 in 1917; Freeport & Mexican Fuel Oil Corporation (Sinclair Gulf Corporation), 4,119,654 barrels, against 4,076,982; East Coast Oil Co., 3,457,236 barrels, against 3,143,221; Cortez Oil Corporation, 2,161,757 barrels; Mexican Gulf Oil Co. (Gulf Oil Corporation), 1,728,190 barrels, against 1,160,794; La Libertad, 1,550,869 barrels; Mexican Petroleum Co. of California, 1,445,977 barrels, against 1,125,702; Texas Co., 1,279,747 barrels, against 2,315,433; Cía. Petróleo Tal Vez (Southern Oil & Transport Corporation), 1,152,064 barrels, against 989,561; International Petroleum Co., 609,734 barrels, against 619,828; Tampascas Oil Co., 578,479 barrels, against 174,925; Panuco Boston Oil Co. (Atlantic Refining Co.), 531,511 barrels, against 828,067.

Exports increased in 1918.—Exports of crude petroleum and refinery products from Mexico in 1918 amounted to 7,677,278 metric tons, valued at $140,557,553, Mexican gold, compared with 6,426,036 tons, valued at $53,676,127, in 1917. The increase in value reflects the higher prices that were paid for Mexican oil, especially for the refined and topped oil. The increase of 1,251,242 tons in 1918 over 1917 represents a gain of 19.47 per cent. Crude oil made up 5,057,556 tons of the total and refinery products 2,619,721, the relation between the two classifications being about unchanged as compared with 1917. The 1917 export record was 4,301,744 tons of crude and 2,124,292 tons of refinery products; the 1916 record was 2,978,103 tons of crude and 1,061,623 tons of refinery products, a total of 4,039,726 tons, making the gain for 1917 more than 50 per cent.

Tampico led all ports in 1918 with 2,837,975 tons of crude and 2,433,038 tons of refinery products exported, a total of 5,271,013, and with a combined value of $100,725,081, Mexican gold. In 1917, exports from Tampico were 2,886,892 tons of crude and 1,896,375 tons of refinery products, a total of 4,783,267 tons, having a combined value of $34,889,273. In 1916 exports from Tampico totaled 2,670,274 tons.

Tuxpam was second, exporting 2,219,581 tons of crude and 36,765 tons of refinery products, a total of 2,256,347 tons, valued at $32,607,810. In 1917 the exports were 1,414,952 tons of crude and 12,266 tons of refinery products, a total of 1,427,118 tons, valued at $12,928,579. In 1916 there were 1,161,643 tons of crude and no refinery products exported.

Puerto Mexico, the southern port through which the Mexican Eagle Oil Co. (Ltd.) makes shipments from its Minatitlan refinery, exported 149,555 tons of refinery products, valued at $7,171,023, as against 207,713 tons, valued at $5,734,453, in 1917, and 220,810 tons of refinery products and 7,000 tons of crude, a total of 227,810 tons, in 1916.

From ports on the west coast of Mexico, Salina Cruz and others, 364 tons of refinery products, valued at $53,631, were exported in 1918, compared with 7,938 tons of refinery products, valued at $122,821, in 1917.

The Huasteca Petroleum Co. led in exports and was closely followed by the Mexican Eagle Oil Co. and the Penn Mex Fuel Co. The Standard Oil Co. of New York was a large shipper of refinery products, principally distillate from the Mexican Petroleum Co.'s Tampico refinery, the total value of its shipments being second to the Mexican Eagle Oil Co.'s, which led in value.

Out of the total of 7,663,639 tons of oil shown as exported to foreign countries, 6,405,731 tons, or about 84 per cent, were shipped to the United States. The slight difference shown in the table of exports from Mexico and the table of exports to the various countries is explained by bunker purchases at the Mexican ports which do not reach foreign destinations.

Record of all completed wells.—A compilation of all borings of which records are available shows a total of 811 wells completed in the Republic of Mexico to the end of 1918. Of this number, 512 were unproductive and 299 were productive. The initial (potential) production of these latter wells is estimated by the department at 253,217.93 cubic meters, or 1,592,740.78 barrels. The actual daily production is 27,801,610 cubic meters, or 174,872 barrels, this representing 10.98 per cent of the potential production. At the end of 1917 the estimated potential daily production of all wells was 212,593.44 cubic meters, or 1,337,212 barrels.

The Mexican Eagle Oil Co. (Ltd.) (El Águila), is credited with the largest number of wells drilled by any one company—a total of 339, of which 284 were abandoned and 55 were productive, these productive wells having an initial output of 20,590.18 cubic meters, or roughly 129,000 barrels.

The Huasteca Petroleum Co. is credited with 23 completed wells, of which 19 were abandoned and 4 were productive. The potential daily capacity of these four wells is given as 48,553.17 cubic meters, or approximately 300,000 barrels.

The Mexican Gulf Oil Co. (Gulf Oil Corporation), with two productive wells, is credited with a potential daily production of 22,370.5 cubic meters, or approximately 140,000 barrels.

The Texas Co. of Mexico has 10 producing wells with a daily potential capacity of 17,072.19 cubic meters, or approximately 107,000 barrels.

The Penn Mex Fuel Co. has seven productive wells, with a daily initial capacity of 13,969.35 cubic meters, or approximately 88,000 barrels.

The Cía. Petrolera de Tepetate (Gibson, Zahniser & Vincent), the majority stock of which was recently acquired by the Atlantic Gulf & West Indies Steamship Co., is credited with two producing wells having a daily potential capacity of 21,462.86 cubic meters, or approximately 135,000 barrels.

Drilling operations in 1918.—Drilling was done during the year on 75 wells in the principal districts of Mexico, as follows: Panuco, 29; Tuxpam, 22; Ozuluama, 12; Topila, 5; Sarlat, 3; Tamaulipas, 2; San Luis Potosi, 1; Tantoyuca, 1.

Forty-three wells were completed, 15 were abandoned, 28 were producing, and 32 still drilling or shut down.

Panuco led in the number of wells completed, with Tuxpam a close second. Panuco is credited with 13 producing wells with a daily potential production of 10,429.25 cubic meters, or approximately 65,000 barrels, while the seven producing wells credited to Tuxpam had a daily potential production of 44,154.98 cubic meters, or approximately 280,000 barrels. The four producing wells in the Ozuluama district are credited with a daily potential production of 23,565 cubic meters, or approximately 150,000 barrels.

The following information is quoted from the 1918 Year Book of the Oil, Paint, and Drug Reporter, pages 309 and 310:

The last month of the year proved to be unique, inasmuch as it saw more large wells completed than had been the case in any other month, and also, it proved to be the month in which the Mexican Eagle Oil Co.'s famous Potrero del Llano No. 4, one of the world's greatest oil wells, went to salt water. This well, completed

December 26, 1910, produced over 100,000,000 barrels of petroleum before salt water suddenly invaded it in the first week of last December. The well is producing an emulsion now of, say, half oil and half salt water, at the rate of 50,000 barrels a day, the rate it was producing free oil when the saline invasion occurred. Its developing the saline emulsion affords the first instance of approximately how long one of the capital wells of this region might last, although in considering the nearly eight years of life of this well, it must also be recalled that for the past four years it has practically flowed "wide open," as the oil seeping up outside of the casing precluded any successful attempt to close it in, or even "crack down" the master gate valve on the 8-inch casing.

Drilling at Panuco during the past year was practically confined to what was considered within the limits of proven territory. In this connection the Isleta sector was demonstrated to be quite narrow, while the 8,000-barrel completion in the Camolote sector awakened interest in this western (by south) edge of the pool.

At Topila, another capital well was drilled in the Tamboyoche sector, near the river, where two big wells were drilled in 1917. One other test drilled at the eastern edge of the same sector was a failure.

LAWS AND TAXES.

On February 19, 1918, the Mexican Government issued a decree, the object of which was to nationalize petroleum lands via the taxation route. This decree set forth the following table of taxes, which it declared would be collectable in the future; and at the same time it provided for the manifestation of all oil lands owned in fee simple or leased. The tax table provided—

(*a*) A percentage of cash rents, varying from 10 per cent, where it is less than 5 pesos per hectare (2.47 acres), to 50 per cent on the excess of 10 pesos per hectare.

(*b*) Five pesos per hectare where no cash rent is paid by lessees.

(*c*) A similar tax of 5 pesos per hectare where the fee owner of unleased property seeks to retain the subsoil rights.

(*d*) Fifty per cent of the royalties under leases.

(*e*) Five per cent of the product from fee owners of unleased properties and the payment of the taxes set forth, in consideration of which the Government would issue permits for the exploitation of same, which would be valid in lieu of the titles to the properties or lease agreements with private owners.

To this all of the major companies, with possibly some four exceptions, demurred; and after a series of interviews with the principal officials of the Government, which, from the viewpoint of the interested companies, were bootless, the companies in question brought injunction suits before the Supreme Court (Amparos) of the Republic asking that the Government be restrained from enforcing its decree of February 19, and the subsequent regulatory decrees based thereon.

EXPORT TAXES.

Effective May 1, 1917, the taxes collectable on export oils were ordered based on New York market prices at the rate of 10 per cent of the valuations so derived, the Department of Hacienda readjusting the valuations every two months. The following valuations were in effect for the months of November and December:

Fuel oil having a specific gravity of 0.91	ton..	$13.00
Crude oil having a specific gravity of 0.91	do..	15.00
Crude oil with specific gravity of 0.97	do..	6.00
Gas oil	do..	13.00
Refined gasoline	liter..	.12½
Crude gasoline	do...	.11¾
Kerosene, crude or refined	do...	.04

The figures presented are in Mexican gold. Petroleum or its derivatives sold in the Republic escapes taxation.

PRINCIPAL PRODUCING FIELDS.

The original producing field in the Tampico region was Ebano. Since then, however, new areas have been developed one by one until there are at this time a dozen or more localities where wells have been brought in, some of them of enormous capacity. Among the principal producing fields are Juan Casiano, Cerro Azul, Panuco, Potrero del Llano, Topila, Aguanacida, Alamo, Tepetape, Chinampa. These fields are stretched along the coast for a distance of about 120 miles and extend back toward the interior as far as 50 miles. Most of the oil is of an asphalt base. The fact that

it does not run high in gasoline content has caused the establishment of several sopping plants for the removal of the gasoline and naphtha, the remainder of the oil being sold for fuel. Refineries are in operation, however, that carry the distilling process to the point that brings forth a large yield of gasoline, leaving a residue of asphalt and other valuable products. During the year 1918 the refining facilities at Tampico were greatly enlarged, and plans are on foot for still further increasing the capacity of the existing plants and the building of new plants during the current year. Much was done during 1918 by the different operating companies in constructing new shipping terminals, installing loading racks, and making general provision for an expansion of their export business. Additional ocean-loading pipe lines were installed in the Gulf outside of the port of Tuxpam; extensive terminals were built at Port Lobos, which seems destined to become one of the principal places of export of the Gulf coast: short lines of railway were built by companies in order to obtain a transportation outlet for the fields where they are operating; and more than 50 miles of modern highway were constructed.

PRODUCTION.

The following statistics are reported by the Petroleum Bureau, Department of Industry, Commerce, and Labor, Mexico City:

Petroleum produced in Mexico, 1901–1918.

	Barrels.		Barrels.
1901	10,345	1910	3,634,080
1902	40,200	1911	12,552,798
1903	75,375	1912	16,558,215
1904	125,625	1913	25,696,291
1905	251,250	1914	26,235,403
1906	502,500	1915	32,910,508
1907	1,005,000	1916	39,817,402

WEST INDIES.

TRINIDAD.

The Trinidad petroleum industry, according to a report issued by the inspector of mines, continued to expand during 1918. The total production of crude petroleum in 1918 was approximately 72,872,398 gallons, as compared with 56,080,914 gallons in 1917. During the war, development operations were carried on with difficulty, and some of the smaller companies suspended operations altogether. It is expected, however, that in 1919 several of these companies will resume activities. The prospects are regarded as very favorable, as some important British interests have recently acquired oil rights over large tracts of land.

The number of new wells drilled in 1918 was 41 (37 on Crown and 4 on private lands), and in 29 of these, oil was found. The number of wells drilled in Trinidad up to the 31st of December, 1918, amounted to 410, of which 236 are on Crown lands. There were 12 producing companies in 1918, as against 11 at the end of 1917.

Exports of crude and refined oil in 1918 amounted to 45,689,234 gallons, as compared with 37,777,919 gallons in 1917.

Petroleum produced in Trinidad, 1908–1918.

CUBA.

Reports on drilling for oil in Cuba for the year 1918 are of a generally unfavorable nature, and lack of material prevented drilling in many places.

DOMINICAN REPUBLIC.

The following discussion of oil possibilities in the Dominican Republic is quoted from the Oil Trade Journal of March, 1919:

A considerable area in the southern part of the island of Haiti, included in the Dominican Republic, has proved to be geologically favorable for the location of productive pools. In one area seepages of oil have been observed for many years accompanied by discharges of inflammable gas that have been the cause of much wonderment to the natives. The only known drilling operations carried on within the Republic, however, were undertaken near Azua in 1904–1906. On account of the low price of crude in the United States at that time, as well as the apparently extensive supplies in the Texas and Louisiana coast districts, with which the Azua field would have entered into competition, capital could not be enlisted to continue the operations.

The oil obtained in the Azua field was of distinctive type, low in gasoline, but with a fairly high percentage of kerosene and the heavier distillates and having a residue of unusual value as a lubricant or low cold test fuel oil, due to the lack of paraffin.

Recent tests of this crude, obtained from a well less than 1,000 feet in depth near Azua, give the following distillation analysis: Specific gravity at 60° F., 0.9390; gravity Baumé, 20.4°; weight per gallon, in pounds, 7.752; amount of sulphur, 3.07 per cent; British thermal units per pound, 18,460; British thermal units per gallon, 143,110; open-cup flash, 185° F.; open-cup fire, 220° F. The initial boiling point was 160° C., and 56 per cent residue remained at 300° C.

When the first test work was done, in 1904, one of the wells made repeated flows of oil over the derrick and was variously estimated as having a capacity of from 500 to 2,500 barrels. Later a flow of water was encountered that could not be handled effectively, and this dampened the ardor of the company conducting the operations.

Recently the Azua district has been the scene of careful geological investigation, and predictions have been made that during 1919 this area will receive a careful test by experienced operators equipped with modern machinery.

CENTRAL AMERICA.

A detailed geologic examination of a large part of Costa Rica and Panama was completed by a subsidiary of the Sinclair Gulf Corporation in 1918 and drilling was begun on Columbus Island near Bocas del Toro, Panama, which is on the Atlantic coast not far from the Costa Rica boundary. Two tests are reported to have been started in Costa Rica, near Limon. Late in the year it was reported that a British corporation had obtained a concession to exploit oil in the north half of Costa Rica.

Concessions covering oil development are reported to have been granted in Guatemala and Honduras, but no active work has been undertaken in these countries.

SOUTH AMERICA.

COLOMBIA.

The following discussions of oil possibilities and development in Colombia are quoted from the Oil Trade Journal of February, 1919, pages 36 and 37, and March, 1919, pages 72–74:

The legal and legislative phases of developing oil properties in Colombia, South America, received much attention during 1918 both from the Government and the companies operating or contemplating investment in that country. Most of the Latin-American countries have as their basic land laws the codes established under the old Spanish régime. In some cases these have been revised by legislative enactment and by executive decree, but some of the republics, as in the case of Mexico, have been inclined to hark back to the Spanish law, which vested in the Government full ownership of subsoil rights.

A measure relative to Government ownership of subsoil rights and, specifically, ownership of petroleum in lands acquired from the Government since 1874, was presented to the last Colombian Congress, which closed its sessions in November, 1918. This act met with spirited opposition. When it became apparent that the bill could not pass in its existing form, the Government appointed a committee, which modified the provisions so that they would apply only to the future and exclusively to Government lands or to land concessions granted by the Government. In other words, the retroactive feature was eliminated. This was satisfactory to all interests, but the congress adjourned without final action having been taken on the bill.

Geological and surface indications of oil are prominent in Colombia. While the Standard Oil Co. of New York spent over $1,000,000 in prospecting districts near the Atlantic coast and gave up this enterprise as unsatisfactory, the work already accomplished at interior points has been successful in certain instances and is promising for the future.

The Tropical Oil Co. (Mares concession) on the bank of the Magdalena River, some 400 miles from the river's mouth, has drilled in several wells rated as good producers. The headquarters of the company is at Barranca Bermeja. This company's plans include the construction of a refinery and the building up of a large domestic trade. An immediate market for fuel oil is seen in the thirty-odd river steamers which ply between Barranquilla and La Dorado, a distance of 600 miles. These vessels now burn wood and are subject to great delay and slow speed.

Less than half of the great area of Colombia is explored. That part of the country lying east of the inside range of the Andes to the Amazon is largely a tropical wilderness, from which explorers and hunters bring reports of oil seepages. Dr. Hamilton Rice, of Newport, R. I., explorer and scientist, is an authority on the country sloping down to the Amazon. He has led two expeditions for exploration of that region, each of which consumed 14 months.

At the foot of the eastern range of the Andes, in the Amazon country, there are known oil seepages. Four days' mule-back from Bogota covers the distance and the oil has frequently been used by travelers in bathing sores on cattle and pack horses.

Location of the Barco concession.—The Barco concession, which was originally taken over by the Carib Syndicate (Ltd.), of New York, and ownership of which is now vested in that company and the Colombian Petroleum Co. (H. L. Doherty & Co.), is situated in Colombia at the Venezuelan border where the Catatumba and Zulia rivers pass from Colombia into Venezuela, emptying into Lake Maracaibo.

The operators of the concessions on the Venezuelan-Colombian border are continually meeting with difficulties in bringing up supplies and machinery through Venezuela. This is the logical routing, but, in the case of a concession on the Colombian side, a factor at present is the frontier dispute existing between Colombia and Venezuela. This controversy has been in evidence for nearly a century, and in spite of agreements, treaties, and all efforts of the Colombian Government there is constant friction between the two countries, with the result that the operators of the Colombian concessions on the border have found it difficult to get the Venezuelan Government's consent to transport machinery by way of Lake Maracaibo. To reach the Barco concession from the Magdalena, a mountain range must be crossed, making the transportation of machinery over that route quite difficult.

In Colombia the American companies have been laying plans for extensive development, the most active being the Tropical Oil Co., at Pittsburgh, the Carib Syndicate (Ltd.), and the operating company of the Barco concession known as the Colombian Petroleum Co. (H. L. Doherty & Co. and Carib Syndicate Ltd.). During the past year actual drilling operations were confined to the locations of the Tropical Oil Co., near Barranca Bermeja, and the Carib Syndicate, near Hond, both locations being in Magdalena River valley.

The credit of having completed the first Colombian petroleum gushers goes to the Tropical Oil Co. The Tropical's four wells, now drilled or drilling, are about 15 miles up Colorado River, a tributary of the Magdalena. The company started exploration work two and a half years ago, and began drilling No. 1 well early in 1917, but was hampered by lack of materials, so that No. 2 well, situated 2 miles from No. 1, was the first to be completed, coming in early in 1918 at 1,525 feet and flowing from 1,500 to 8,000 barrels a day through three strings of pipe. It was successfully shut in. No. 1 well was completed late in 1918. It was drilled to 2,270 feet, and came in as a gusher, shooting oil over the derrick and flowing four and a half hours before being shut in. This well is variously rated from 2,000 to as high as 20,000 barrels. No. 3 well, located about a mile from No. 1 on a diagonal line, struck oil at 900 feet, but caught fire, and the derrick was destroyed. No. 4 is now drilling. The oil is dark in color and has some asphalt in its composition, but gives a good yield of gasoline.

The Tropical Co. has under consideration the building of a pipe line from its concession to Cartagena, as well as the construction of a refinery in Colombia capable of handling its oil. Tests of the oil from well No. 1, which is a light-grade crude of 36° Baumé, showed an approximate yield of 30 per cent of gasoline 58° and above, 32 per cent gravity amber oil per day, sufficient to operate a small local refinery on the property.

An analysis of this seepage oil shows gasoline, 24.4 per cent; kerosene, 18.4 per cent; fuel oil, 22.1 per cent; light machine oil, 6.4 per cent; lubricating oil, 12.4 per cent; cylinder stock 15.2 per cent; loss, 1.1 per cent.

VENEZUELA.

The following is quoted from the Oil Trade Journal of April, 1919, page 72, and March, 1919, pages 74–76:

CARIBBEAN PETROLEUM'S OPERATIONS IN VENEZUELA.

With a view to developing the local oil industry in Venezuela and supplying the adjacent and foreign markets with petroleum products, the Caribbean Petroleum Co., a subsidiary of the General Asphalt Co., in which the Royal Dutch-Shell group is also interested, for several years past has carried on quite extensive operations in that country. This work has been conducted in both eastern and western Venezuela, but principally in the western section of the country, extending roughly around the whole perimeter of Lake Maracaibo.

Systematic geological surveys of the western section of Venezuela, along the eastern shore of Lake Maracaibo and 50 miles to the westward of the lake, were made under the supervision of Dr. Ralph Arnold. Oil-bearing areas were found mostly in the wild and undeveloped portions of the country, which hampered the preliminary investigation work and called for the utmost zeal and patience in combating the ever-present natural obstructions of the tropical jungle. In January, 1914, the first test well was drilled to shallow depth, passing through several beds of rich sands showing oil of good quality. Encouraged by this result, several deeper wells were later sunk until a satisfactory production of oil has been obtained.

To facilitate the handling of petroleum, storage tanks and a pumping station have been erected, as well as a pipe line connecting the Mene Grande field with the shipping point at San Lorenzo, on the eastern shore of Lake Maracaibo, a distance of about 11 miles. Despite the exigencies of war and the resultant shortage of labor, a modern refinery also has been erected at San Lorenzo, equipped with the latest appliances. In addition to the refinery, a factory has been built for the manufacture of containers. These plants are meeting the local needs of Venezuela, and an experienced sales department has been organized and is marketing petroleum products throughout that country.

A wharf with an extension pipe line and pumping station is part of the equipment at this point, and was erected to facilitate the export trade. By this arrangement the company is able to deliver aboard steamships and lighters a substantial quantity of oil per hour.

One of the most important undertakings of the company is the erection of a large refinery on the Island of Curaçao, lying off the north coast of Venezuela. This plant is constructed on the Trumble system and embodies the latest refining methods. During the war the work was seriously hampered by difficulties experienced in obtaining materials, due to the lack of transportation facilities, but the plant is now practically completed. The first large cargo of Venezuelan petroleum was delivered from Curaçao in January, 1918.

Upon the acquisition of high-powered tugs and the delivery of two more large barges, now nearly ready, transportation between Venezuela and Curaçao will be much increased, the latter point becoming the shipping point for foreign markets. Every provision is being made to handle miscellaneous petroleum products and bunker oil for vessels using the Panama Canal. Distributing stations have also been erected at La Guayra, Puerto Cabello, and Maracaibo, in Venezuela.

Along the coast of Venezuela, and extending several hundred miles to the west, are found important seepages of asphaltic oil. These indications have been carefully checked by geologists employed by operating interests in Venezuela, generally known as the Royal Dutch-Caribbean Petroleum group. A number of concessions have been granted by the Venezuelan Government for the exploitation of these areas, and were it not for the rather unsettled political conditions in Venezuela, development and testing work would be much further advanced.

The Caribbean Petroleum Co., which is owned jointly by the General Asphalt Co., of Philadelphia, and the Royal Dutch interests, is by far the most active developer of Venezuelan oil. Two prolific areas have been discovered by this company on opposite shores of Lake Maracaibo; a refinery sufficient to deal with the needs of Venezuela, with a modern plant for packing oil in tins, has been completed at San Lorenzo, on the eastern side of the lake; and a line of barges to transport crude oil to the Royal Dutch refinery on the near-by Island of Curaçao has commenced deliveries of Venezuelan oil on a substantial scale. The Caribbean petroleum organization has already spent several millions of dollars in preparing for a development of South American business.

The refinery at Curaçao is modern, and is located at the end of a deep bay that will accommodate tankers of large size. Its capacity is estimated at 10,000 barrels daily. The location of this expensive plant on an isolated island which has small chance of becoming of itself a producer of crude was probably due to the lack of suitable harbors near the Venezuelan production, reinforced by the consideration that until political conditions are more stable in Venezuela the plant would be safer on Dutch soil.

The entrance to the Venezuela fields of the Maracaibo basin is through an extensive stretch of shallow water known as the Venezuelan Gulf, and then through a channel with a minimum depth of 12 feet into the fresh-water lake of Maracaibo. Permanently to deepen this channel would be extremely difficult, and this has made barging of the crude necessary. It is expected, however, that a more satisfactory loading berth will eventually be provided on the west shore of the Venezuelan Gulf, to which a pipe line can be laid from the producing areas. The crude thus far produced is of very dark color and of varying gravity and generally of asphaltic base near the coast. * * *

At least two of the three wells of the Colon Development Co. are said to be of large capacity from depths of less than 1,300 feet. The producing formation is sandstone, and the wells are of the gusher type. One of them, on the Rio del Oro, is reported to have flowed between 1,500 and 2,000 barrels in 24 hours through 8-inch pipe with the drill in the top of the formation. The oil is about 36° Baumé, with a good yield of gasoline and kerosene, and has a paraffin base.

Another small development near San Cristobal has yielded for a number of years a small quantity of crude that is used locally.

Petroleum produced in Venezuela in 1917 and 1918.

Year.	Quantity.		Value.
	Barrels.	*Metric tons.*	
1917	127,743	17,742	$145,984
1918	190,080	26,400	211,200

GUIANA.

According to a report by Consul George E. Chamberlin dated June 18, 1918, the following article appeared in the Daily Argosy of Georgetown, under that date:

It is understood that the Venezuelan Oil Concessions (Ltd.), an English company operating in Venezuela, of which Viscount Cowdray, president of S. Pearson & Sons, in many parts of the world, is the head, has secured from the Colonial Office a large concession in the North West District to explore for oil. The area aggregates something like 2,000 square miles.

At present the company has a large staff of mineralogists, surveyors, and geologists prospecting for oil in Venezuela. It is understood that before the end of the year the party is likely to visit this colony with the necessary equipment to carry on exploration work.

ECUADOR.

According to a recent report from United States Consul General Frederick W. Bolden, of Ecuador, petroleum is now used for fuel at a brewery and electric-light plant, at which about 25,000 barrels are burned each year. At Guayaquil and Quito railway officials have also decided to change the locomotives from coal burners to oil burners.

Exploration of the petroleum of Ecuador has been carried on for some years by the geologists of the Lobitos Oil Fields Co. (Ltd.), which has acquired a large area of promising territory lying along the seashore. It is reported that in this property, besides surface indications, one well has been sunk which reached the oil sand at a little more than 2,000 feet and furnished a moderate production.

PERU.

The production of petroleum in Peru in 1918 was 2,536,102 barrels, a very slight increase as compared with the production in 1917. Increase in production is reported from Negritos and Zorritos fields, and a slight decrease from the Lobitos fields. The development during the year followed along lines already standardized by the companies which have been operating there for some years past and no new work of special significance was undertaken.

Petroleum produced in Peru, 1909–1918, in barrels of 42 gallons each.

ARGENTINA.

The output of petroleum in Argentina in 1918 was 1,321,315 barrels, an increase of 176,578 barrels, or 15 per cent, as compared with the output in 1917. According to an article in the Review of the River Plate of May 23, 1919, the increase would have been considerably more had it not been for the stoppage of work by reason of a strike. Twenty-five new wells were completed and three were deepened, a relatively small record owing to the difficulty of obtaining drilling materials and piping. Manufacture of piping in Argentina has been attempted but without satisfactory results. A plan of work has been formulated to increase the output and for the erection of a refinery, purchase of tank steamers, and acquisition of new machinery of a general nature, and for increased development in all phases of the work.

Government oil fields were operated by the Dirección general de la explotación del petróleo de Comodoro Rivadavia, Department of Agriculture, Argentina. In addition to the Government-operated fields, two private companies produced small quantities of petroleum during 1918—the Compañía argentina de Comodoro Rivadavia and the Astra Co.

Petroleum produced in Argentina, 1909–1918.

Year.	Metric tons.	United States barrels.	Year.	Metric tons.	United States barrels.

EURASIA.

RUSSIA.

Information concerning petroleum operations in Russia during 1918 is very meager. The following is an estimate of the production of the Baku fields published by the Petroleum Times on March 8, 1919:

1918.	Poods.	1918.	Poods.
January	28,573,739	August	11,207,224
February	22,745,368	September	5,666,816
March	20,000,000	October	9,529,413
April	17,700,000	November	11,683,727
May (18 days)	10,918,041	December	12,377,067
June	17,564,684		
July	17,225,915		185,191,994

These figures do not include the wells dug by hand. As the production of these is estimated at about 1,000,000 poods a month, the total of the whole of the Apsheron Peninsula may be taken at 200,000,000 poods for the year 1918.

On February 22, 1919, the Petroleum Times published the following article concerning the Maikop fields:

We understand that a telegram dated Apscheronskaia, January 15, 1919, has been received by the Anglo-Maikop Corporation from their chief engineer in Russia, stating that the general and financial position of the companies under its control is good, that the oil properties are practically intact, and that production has been carried on throughout the year.

The production of the principal allied companies for the year 1918 has been as follows: Maikop Combine, 1,980,000 poods; Black Sea Amalgamated Oilfields, 980,000 poods. The present normal daily production of the Maikop Combine is 7,000 poods and of the Black Sea Amalgamated Oilfields 3,000 poods.

The recently completed new well No. 6 of the Maikop Combine is giving a daily production of 1,300 poods. In the new well No. 4 of the Black Sea Amalgamated the water has been successfully shut off; well No. 5 is in drilling depth 925 feet; and work on well No. 6 is expected to start soon.

Maikop Pipe Line & Transport Co. continued pumping regularly throughout the year.

The price of crude oil at Ekaterinodar has been increased since September to 7 roubles a pood and pumping charges to 52 kopecks a pood.

Petroleum produced in Russia, 1909–1918.

RUMANIA.[1]

At the end of November, 1916, the Rumanian armies were forced to abandon Walachia to the invading enemy. Accordingly, the Government of that country agreed with its allies that destruction of the petroleum equipment was necessary in the superior interest of the national defense in order that the enemy might not continue the production and refining of oil and thus control a powerful force against Rumania itself and its allies. Measures were therefore taken by an Anglo-Rumanian commission to plug all the productive wells, to burn the oil reservoirs and their contents, and to completely destroy the refineries.

On taking possession of our oil fields the enemy saved a part of the equipment that was then in flames, but most of the refineries and wells were either totally destroyed or so badly damaged that they could not be operated without restoration or extensive repairs. Only such equipment as could not be burned without hindering or imperiling the safe retreat of the Rumanian armies was left intact.

A complete reorganization of the petroleum industry was begun as soon as the armies of the enemy occupied the oil fields, and in February, 1917, the first well was reopened in Campina, and others soon followed in the same and other districts. Because of the

[1] The Rumanian petroleum industry during the last three years and its present state: Moniteur du pétrole roumain, vol. 18, pp. 3, 6–7, July 15, 1919.

wealth of technical information available and of the personnel of enemy specialists who knew the conditions of the industry in our country, a small production was obtained within a relatively short time, but the difficulties of obtaining production of any importance were very great.

Within a short time the two largest refineries of the country, the Steaua Romana of Campina and the Vega of Ploesti were put in working order, and the refining industry was restored to some extent sooner than one would have believed possible. * * *

Granting the Rumanian petroleum industry the importance which the German staff accorded it, as the only source of that product indispensable to the continuation of its submarine warfare as well as for fuel for its other enterprises and for its entire park of aviation and automobiles, it is easily understood what activity the German military administration developed. A special body was created for handling this matter, called "Kommando der Erdölfelder in Rumänien" (Command of petroleum exploitation in Rumania)—abridged to "Kodöl"—and also a special section called "Mineralöl-Abtheilung" of the military adminstration of Rumania.

The first body, with headquarters at Campina, occupied itself with all questions regarding operation and development, the regulation of the industry, and the furnishing of working material; the second body, with headquarters at Bucharest, had charge of the refining of crude petroleum, its apportionment by destination, and the transportation of its products into Germany or the other countries allied with her.

All companies and enterprises were requested to begin at once to restore their lands and to put their wells in working order. Those who did not conform to this order were warned that the military administration would take over their properties or would put them under contract. Sequestrators, who directed operations under the supervision of the military administration, were named for those companies and enterprises that remained loyal to the allies of Rumania.

* * * By November, 1918, the enemy had restored to production 437 wells out of a total of 962 in existence on July 1, 1916, a proportion of about 45 per cent. * * * This proves that the German military administration concentrated all its efforts on the richest wells that had been salvaged and restored to productivity. Out of 341 wells drilling on July 1, 1916, the Germans continued work on 220.

BRITISH ISLES.

Particular interest attaches to the search for oil in Great Britain, not only from the great advantages that would accrue to Great Britain from the production of oil within the country itself but also because of the great scientific interest which has been taken in the drilling for oil in that country. An agreement was made between the ministry of munitions and Messrs. S. Pearson & Sons, bearing date of September 10, 1918, wherein it was laid down that the petroleum development managers should commence the development of not exceeding 30 areas for the purpose of production of petroleum, after they had been examined by Sir John Cadman, the firm of S. Pearson & Sons acting as petroleum development managers. In all, 11 drilling sites were selected, of which 7 were in Derbyshire, 2 in

North Staffordshire, and 2 in the Mid-Lothian district of Scotland. Two wells were begun in 1918 in Derbyshire—the Hardstoft well on October 15 and the Brimington well on November 29, 1918.

1 metric ton, crude=7.1126 barrels.

PERSIA.

The following extract is from the report of the chairman of the board of directors of the Anglo-Persian Oil Co. (Ltd.), as recorded in the Petroleum Times of March 29, 1919:

The wells in the field from which we have hitherto been obtaining our production still maintain their extraordinary high rate of yield, and the wells already drilled are, it is estimated, capable of yielding a production at the rate of 5,000,000 tons per annum. On the field adjacent to it, to which I referred at the last meeting, another well at a distance of about 1 mile from the preceding one, has struck oil in considerable volume, the well being reported upon as being equal to any yet struck in the company's territories. In the third field, referred to in my last speech, little progress has since been made, owing to the lack of drilling material, but the prospects are still satisfactory. Testing operations are being carried on, or are about to be started, in a further six fields, all of which give promise of favorable results. You will also be interested to learn that we are now substituting electric for steam power in our producing fields—a change which will result in greater efficiency and a minimum of cost for drilling and producing generally.

Since I last addressed you the first of the refinery extensions at Abadan, to which I then referred, has been completed and brought into operation. The further extensions, for which capital was issued a little over 12 months ago, have not yet been completed, owing to the great delay which has been experienced in obtaining delivery of plant, but they are now well in hand and should be completed during the year. A further large addition at Abadan has now been decided upon to enable us to meet the rapidly growing demand in the East for our fuel oil and will be undertaken as soon as plant can be contracted for at reasonable prices and delivery.

In addition to our extensions at Abadan, we have now commenced the erection of a large refinery near Swansea, where the refining of such products as are marketable in the United Kingdom can be carried on more thoroughly and more economically than at Abadan. The work at this refinery, the initial capacity of which will, I may mention, be twice that of the whole of the Scotch shale oil companies, is being executed with all possible speed.

The additional pumping stations referred to by me at the last meeting are now in course of erection, and should be in operation during the course of this year. We have also decided upon the laying of an additional 10-inch line from the fields to our present 8-inch line, in place of the present 6-inch line, which will further considerably augment our pipeage capacity between the fields and the Persian Gulf. We shall, when this line is completed, have one complete 10-inch line from the fields to the Gulf and another line made up of 10-inch pipe for about half the distance and 8-inch for the remainder.

Our fleet now amounts to a total dead-weight capacity of 162,000 tons, and, as mentioned in the report, we have placed orders for further vessels of a total capacity of about 150,000 tons. We also purpose purchasing further ready tonnage whenever opportunities occur for securing it at reasonable prices. All of our vessels which were requisitioned by the Shipping Controller have now been released, and such as are not required at the moment for our own transport work have been chartered at remunerative rates.

Petroleum produced in Persia, 1917 and 1918.

Year.	Barrels.	Metric tons.

BRITISH INDIA.

The following report concerning the development of the oil industry in India is taken from the annual report of the chairman of the board of directors of the Burmah Oil Co. (Ltd.), as published in the Petroleum Times of June 28, 1919:

Principally on account of the enforced curtailment of our drilling and testing program I have really not very much to say to you to-day in connection with our field operations. In common with all the other oil companies operating in Burma, our efforts during the year were mainly concentrated on the Beme district in the Yenangyoung field, where, as I told you last year, an unexpectedly rich sand was struck at about 2,500 feet. Already, however, the territory is showing signs of the severe drain that has been put upon it, and though some wells still come in with large initial production, they as a rule fall off very rapidly. In regard to our crude oil position generally, though I feel it is rather superfluous for me to say anything on that subject in view of what I have said on more than one occasion in recent years. I can to-day confidently say that our drilling operations every year go to still further strengthen our belief that in our proved oil lands in Burma we have ample reserves of oil to enable us to carry on our refining operations on their present scale for very many years to come.

Of our field operations without Burma I much regret that I can not give you anything in the nature of cheering or encouraging news. We have finally abandoned one of the districts we were testing in India, after drilling to a depth of 2,660 feet without finding any oil. In another district under test in India we have reached a depth of fully 1,300 feet without encountering any oil. In the district in Assam, where, to begin with, we struck oil in fair quantities but of very poor quality and where during the past two years we have been struggling against water difficulties in every well, it has at last been conclusively proved that, owing to the poor quality of the oil, the small production per well, and the presence of so much water with the oil, the field can not be made to pay under present conditions and that the only hope of success lies in the possibility of striking oil in much larger quantities and free from water troubles at greater depths, and we are now arranging to test this possibility by drilling deeper.

JAPAN AND FORMOSA.

The production of petroleum in Japan and Formosa in 1918 amounted to 2,449,069 barrels, a decrease of 433,309 barrels, or 15 per cent, as compared with the output in 1917. The decrease was due primarily to the suspension of wildcat drilling on account of the shortage of drilling material and casing. With the removal of the export restrictions by the United States at the close of the war, plans were under way for further explorations, and it is to be assumed that production will soon return to normal.

Prices of petroleum and petroleum products in Japan advanced very markedly during the war. The following table of average prices is published by the Petroleum Times (Sekiyu-Jiho) of Tokyo (February, 1919, p. 2):

Average prices of petroleum products in yen per koku in 1916, 1917, and 1918.

	Naphtha.	Kerosene.	Neutral.	Fuel oil.	Lubricating oil.
	Yen.	*Yen.*	*Yen.*	*Yen.*	*Yen.*
1916	28.00	19.25	11.25	4.00	11.35
1917	32.00	19.50	12.00	7.00	12.00
1918	44.00	25.00	18.00	15.00	30.70

1 yen=49 cents. 1 koku=47.6 United States gallons=1.136 United States barrels.

The following figures are reported by the Imperial Mining Bureau of the Department of Agriculture and Commerce, Tokyo:

AFRICA.

EGYPT.

The following report concerning the production of petroleum in Egypt is taken from the Petroleum Times, July 5, 1919, page 8:

The total production of crude oil for the year amounted to 277,300 tons, as compared with 134,500 tons in 1917.

The increase in the production has necessitated the creation of more storage and refining facilities on the Hurghada fields and at Suez. Some of these have been completed and others are still in course of erection. Another unit is also being added to the refinery at Suez, the material for which is already on the way to Egypt.

Although so far the results have improved from year to year, your directors wish again to emphasize the fact that the present concessions of the company are very limited in extent and that, if a lasting oil industry is to be built up in Egypt, the larger areas for which application has been made to the Egyptian Government are essential. Our views on this subject have been laid before the Egyptian Government, and when the conditions in the country are more settled it is hoped that the question may become the subject of active negotiations and that a satisfactory settlement may be reached.

Petroleum produced in Egypt, 1911–1918.

OCEANIA.

DUTCH EAST INDIES.

The production of petroleum from the Dutch East Indies in 1918, as reported by De Bataafsche Petroleum Maatschappij, was 13,284,936 barrels, a slight increase as compared with the production in 1917. Marked decrease is reported from Java and Sumatra and an increase from Borneo. The portion of the oil produced in the three islands is as follows: Borneo, 60 per cent, Java, 12 per cent, Sumatra, 27 per cent.

ABRASIVE MATERIALS.[1]

By Frank J. Katz.

INTRODUCTION.

Industrial operations employ a great variety of abrasive materials. This chapter is concerned with only those mineral products which, as such or as essential constituents of manufactured products, are used for grinding and polishing and other abrasive operations and as cleansers or detersives. The chapter contains statistics of production, as to both quantity and value, either of the raw material alone or of material that has not been advanced beyond that stage of manufacture at which it is sold by the mine or quarry operator.

Artificial abrasives are included for comparison and because of their strong influence on the industry and markets of natural abrasives.

The statistics here given relate, so far as possible, only to that part of the output of any mineral material that properly enters into the abrasive industries. Thus only a small percentage of the sandstone quarried is used in the manufacture of abrasives, grindstones, and pulpstones, the remainder being used chiefly in the building industry. The segregation of the product is not difficult for sandstone, but there is difficulty in separating the diatomaceous (infusorial) earth which is used strictly for abrasive purposes from that which is used in manufacture of filters or of insulating or fireproofing material, and of this product the total output must be included.

On the other hand, quartz and feldspar, both of which are used as abrasives, are excluded from this discussion because precise separation of these materials according to their uses can not be made. They are used principally for purposes other than abrasive, and therefore they are considered in other chapters.

The preparation of this report has been delayed because the author has been assigned to other duties, which were necessarily given precedence. The delay has, however, made it possible to include certain estimates on the production in 1919, and additional information concerning the industry in 1918.

CONSUMPTION.

Complete figures on the total value of the abrasive materials considered in this report that entered into trade in 1918 are not available because of the refusal of a large manufacturer of artificial abrasives to report production for the second half of the year. This

[1] Miss A. T. Coons and Miss F. E. Taylor have aided in the compilation of statistics in this report. The data on imports and exports were compiled by J. A. Dorsey from the records of the Bureau of Foreign and Domestic Commerce, U. S. Department of Commerce.

total value may, however, be reported as between $11,000,000 and $12,000,000 and a moderate increase over the $11,334,710 total for 1917. This increase was in domestic natural abrasives and in imports, which combined more than offset a decrease in artificial abrasives.

Among the natural abrasives large gains were shown in grindstones and pulpstones, millstones and chasers, and garnet, and there were gains also in oilstones and scythestones, pumice, and grinding pebbles. These gains were largely attributable to increased prices, although there were increases in the quantities also of some of the commodities, as will be shown in subsequent sections of this report. There was a decline in the domestic production (quantity and value) of emery and corundum, diatomaceous earth, tripoli, and tube-mill lining.

Value of all abrasive materials[a] consumed in the United States, 1908–1918.

Year.	Natural abrasives.	Artificial abrasives.	Imports.	Total value.
1908	$1,074,039	$626,340	$476,073	$2,176,452
1909	1,329,750	1,365,820	653,779	3,349,349
1910	1,406,805	1,604,030	977,718	3,988,553

NATURAL ABRASIVES.

Under the head of natural abrasives in this report are included millstones and related quarry products (such as chasers and dragtones), grindstones and pulpstones, oilstones and scythestones, corundum and emery, abrasive garnet, diatomaceous (infusorial) earth and tripoli, pumice, and pebbles and lining for tube mills. The difficulty of separating abrasive quartz and feldspar from the quartz and feldspar produced for other purposes has led to their omission from the chapter on abrasives, and such information as appears about them in Mineral Resources will be found in chapters entitled "Feldspar" and "Silica (quartz)."

Natural abrasives were produced in 1918 in 26 States, which are listed below:

Arkansas	Oilstones.
California	Diatomaceous (infusorial) earth, grinding pebbles, and pumice.
Connecticut	Diatomaceous (infusorial) earth.
Idaho	Diatomaceous (infusorial) earth.
Illinois	Tripoli.
Indiana	Oilstones and rubbing stones.
Kansas	Pumice.
Kentucky	Hones.
Maryland	Millstones.
Michigan	Grindstones and scythestones.
Minnesota	Grinding pebbles and tube-mill lining.
Missouri	Tripoli.
Nebraska	Pumice.
Nevada	Diatomaceous (infusorial) earth and grinding pebbles.
New Hampshire	Garnet and scythestones.
New York	Diatomaceous (infusorial) earth, emery, garnet, and millstones.
North Carolina	Corundum, emery, garnet, and millstones.
Ohio	Grindstones, pulpstones, oilstones, and scythestones.
Oklahoma	Tripoli.
Pennsylvania	Grinding pebbles, millstones, and rottenstone.
Tennessee	Tube-mill lining.
Utah	Diatomaceous (infusorial) earth and "mineral soap."
Vermont	Scythestones.
Virginia	Diatomaceous (infusorial) earth, emery, and millstones.
Washington	Diatomaceous (infusorial) earth.
West Virginia	Grindstones and pulpstones.

Value of natural abrasives produced and marketed in the United States, 1914–1918.

Abrasive.	1914	1915	1916	1917	1918
Millstones	$43,316	$53,480	$44,559	$43,489	$92,514
Grindstones and pulpstones	689,344	648,479	766,140	1,147,784	1,776,282
Oilstones and scythestones	167,948	115,175	154,573	168,704	189,033
Emery (also corundum in 1917 and 1918)	2,425	31,131	123,901	241,050	112,878

b Exclusive of considerable production for special uses upon which the Geological Survey is not at liberty to report. Figures for 1917 revised in 1918.

MILLSTONES.

PRODUCTION.

The value of the millstones (burrstones) and related quarry products—chasers, dragstones, and pavers—sold in the United States in 1918 amounted to $92,514, an increase of 113 per cent as compared with 1917. The production in this country in 1918 was greater than in any other year since the setback in the millstone market in the late eighties, which was due to the introduction of modern grain-milling machinery. This setback has been offset to some extent in the last 20 years by the growing use of millstones for grinding mineral products, such as feldspar, quartz, and pigments.

American millstones have been and are still for the most part made of quartz sandstones and conglomerates. Some are made of granite. The product recorded in the Survey's reports on mineral resources is only that which has been made for other than purely local use. A small number of stones for local use have been made of hard quartz or other rocks, particularly in the mountain sections of the Southern States.

Millstones and chasers were produced in 1918 in Maryland, New York, North Carolina, Pennsylvania, and Virginia. These States and Alabama are the only ones that have produced millstones in recent years. The value of the output in New York increased about 15 per cent, in Virginia there was also a large increase, and in North Carolina there was a very large increase over 1917; in Pennsylvania, the increase was small.

Value of millstones produced and marketed in the United States, 1913–1918.

State.	1913	1914	1915	1916	1917	1918
Alabama	(a)	(a)	.....	(a)	(a)	.....
Maryland	.....	.....	.....	.....	.....	(a)
New York	$21,987	$16,748	$16,883	$10,287	$22,103	$25,488
North Carolina	8,772	5,164	(a)	(a)	(a)	39,224
Pennsylvania	(a)	(a)	(a)	(a)	(a)	(a)
Virginia	23,530	20,100	23,170	25,752	18,980	(a)
Combined totals	1,874	1,304	13,427	8,520	2,406	27,802
	56,163	43,316	53,480	44,559	43,489	92,514

a Included in "Combined totals."

Value of millstones produced and marketed in the United States, 1909–1918.

1909	$35,393	1914	$43,316
1910	28,217	1915	53,480
1911	40,069	1916	44,559
1912	71,414	1917	43,489
1913	56,163	1918	92,514

IMPORTS.

The value of millstones imported for consumption in the United States in 1918 was a little larger than in any other year since 1913, but less than in 1913 and earlier years. In 1918 there was a small increase in the imports of material in the rough and a larger increase in the imports of finished stones.

Value of burrstones and millstones imported for consumption in the United States, 1913–1918.

Year.	Rough.	Made into millstones.	Total.	Year.	Rough.	Made into millstones.	Total.
1913	$36,276	$3,922	$40,198	1916	$15,495	$4,321	$19,816
1914	14,291	709	15,000	1917	17,048	1,179	18,227
1915	16,045	982	17,027	1918	17,570	2,447	20,017

MILLSTONE INDUSTRY.

Prior to 1918 the millstone industry underwent little change from year to year. Therefore, the statements made in the reports for 1909 and for 1913 may be consulted to supplement the data for 1918 given here. In those earlier reports descriptive notes were given on the millstone industry in New York and Virginia. The data obtained on the production of millstones in 1918 indicate a change in the industry. In previous years more of the large stones used chiefly for the grinding of mineral products, earths, and pigments had been quarried and manufactured than of the similar stones used chiefly in milling grains. Although the production of large stones appears to have increased when measured by value of product in New York and Virginia, the greater part of the production for 1918 appears to have been in the manufacture of stones for milling. This increase was chiefly notable in North Carolina, and the change was probably due primarily to war conditions, which demanded an increase in the number of small grain-milling establishments or, at any rate, an increase in the capacity of such establishments in some sections of the country. The industry in 1919 remained about as in 1918, and the production is still, as in other years, in the hands of small operators in Ulster County, N. Y., Montgomery County, Va., and Rowan, County N. C.

New York.—For many years Ulster County, N. Y., led in the production of millstones and chasers (stones which run on edge or on a horizontal shaft), but in recent years the State has yielded first place to Virginia in the production of millstones, although still leading in the output of chasers. In 1918 New York held third place in the order of value of total output. Fourteen operators reported production of millstones, and six reported also production of chasers.

Virginia.—Virginia held second place in order of value of total output in 1918. Only two operating firms or individuals reported production, both in Montgomery County.

North Carolina.—North Carolina held first rank in the total output of millstones in 1918. Eight operators reported product valued at $39,224. The stones were made in Rowan County, in the vicinity of Salisbury, and were granite stones, chiefly for grain milling.

Pennsylvania.—In Lancaster County, Pa., a quartz conglomerate that has been known to the trade as Cocalico stone is made into millstones. Two manufacturers reported production in 1918.

Alabama.—Near Dutton, Jackson County, Ala., millstones have been made from sandstones of Pennsylvanian age. None were made in 1918.

Vermont.—A quartz conglomerate rock similar to the New York Esopus grit is found near Fair Haven, Rutland County, Vt. No millstones have been made of this rock in recent years.

Ohio.—At Peninsula, in Summit County, Ohio, a white variety of the Berea sandstone was formerly quarried for the purpose of grinding oatmeal and pearling barley, for which it was said to be especially well adapted. At present no millstones are made from the Berea sandstone.

Other States.—In many other States stones of different varieties and more or less suitable for coarse work are or have been quarried and fashioned for use in local mills.

GRINDSTONES AND PULPSTONES.

PRODUCTION.

The value of grindstones and pulpstones produced and sold in the United States in 1918 was $1,776,282. This was the largest annual output ever recorded and was an increase of $628,498, or nearly 55 per cent, as compared with 1917. The increase was in both quantity and value of both grindstones and pulpstones.

The States and number of quarries producing grindstones in 1918 were Michigan, 2; Ohio, 19; West Virginia, 3. Ohio, as usual, maintained the leading position in the industry, the value of her output being nearly six times that of Michigan and West Virginia combined. The principal producing regions in Ohio are in Lorain, Cuyahoga, and Washington counties. Some stones are also produced in Holmes, Morgan, and Summit counties. The West Virginia product is obtained chiefly from Jackson County, and there is a small output from Wetzel County. Michigan grindstones are all obtained in Huron County.

The production of grindstones in 1918 amounted to 56,554 short tons, valued at $1,262,602, an increase of 2,122 tons, or 4 per cent, in quantity and of $455,706, or 56 per cent, in value as compared with 1917.

Data on the value of quarry products manufactured into grindstones which have been reported to the Geological Survey for recent years indicate that the common unit of value—that is, the value per short ton—varies 15 to 25 per cent, according to the quality and size of the stones, the smaller stones selling at prevailingly higher prices. Stones range from less than a foot in diameter and less than a pound in weight to 6 and 7 feet in diameter, 1 foot or more in thickness, and between 1¼ and 2 tons in weight. In 1917 the prices of fashioned stones not mounted, as reported by the quarry operators, ranged between $12 and $20 a short ton, but were mostly between $13 and $18. Corresponding figures for 1918 were $16 and $38 as the extremes and $19 to $23 as the predominant prices. The average value of all grindstone material sold in 1917 was $14.82 a short ton, and in 1918 it was $22.33.

Prices for 1919 on small stones increased approximately 10 per cent during the year. On other stones, as marketed unmounted by the producer, prices ranged from $20 to $40 a ton, though the average for the year was between $22 and $25—approximately the same as for 1918, but for some grades a little less than prices at the peak of the war demand late in the summer of 1918.

The American grindstone output is chiefly of two kinds—stones for hand grinding, recutting, and similar work, and stones used for machine grinding in such industries as the manufacture of saws, machine knives, edge tools, and harvester machinery.

The production of grindstones for hand grinding was much retarded during the war, does not appear to have recovered materially, and locally has even further decreased in 1919. On the other hand, the production of grindstones for use in manufacturing was enormously augmented during the war, but in the first half of the 1919 season the demand fell far below normal because of the stoppage of war industries and also because large consumers were well stocked

by heavy buying during 1918. During the later part of 1919, however, demand and production had been restored to about pre-war level.

The production of grindstones is of course a seasonal industry in that the quarries are open cuts in northern latitudes and the freshly quarried sandstone can not be safely handled in freezing weather.

Pulpstones are heavy grindstones used for grinding wood into fine fiber for making pulp and paper. The standard size of pulpstones for certain types of machines is 27 inches in thickness by 54 inches in diameter and about 2 tons in weight. Machines of other types require stones 54 inches in thickness by 62 inches in diameter and about 4 tons in weight.

Pulpstones in 1918 were made by the International Pulpstone Co., at East Liverpool, Columbiana County, Ohio; by the Smallwood Stone Co., at Empire, Jefferson County, Ohio, and at Opekeska, Monongahela County, W. Va.; by the Ohio Buff Sandstone Co., at Sherodsville, Carroll County, Ohio; by the Cleveland Stone Co., at Peninsula, Summit County, Ohio; and by the American Stone Co., at Littleton, Wetzel County, W. Va. The total output was 2,921 stones, valued at $513,680, an increase of 26 per cent in the number of stones, as compared with 1917, and of 320 per cent over 1915. This notable growth was probably due largely, if not altogether, to the difficulty and high cost of importing stones from Great Britain. (See table of imports below.)

Grindstones and pulpstones produced and sold in the United States, 1915–1918.

Year.	State.	Grindstones.		Pulpstones.	
		Quantity (short tons).	Value.	Quantity (pieces).	Value.
1915	Michigan, Ohio, and West Virginia	42,623	$564,340		
	Ohio			696	$84,139
1916	Michigan, Ohio, and West Virginia	50,839	631,497		
	Ohio			1,066	134,643
1917	Michigan, Ohio, and West Virginia	54,432	806,896		
	Ohio and West Virginia			2,325	340,888
1918	Michigan, Ohio, and West Virginia	56,554	1,262,602		
	Ohio and West Virginia			2,921	513,680

Value of grindstones and pulpstones produced and marketed in the United States, 1909–1918.

1909	$804,051	1914	$689,344
1910	796,294	1915	648,479
1911	907,316	1916	766,140
1912	916,339	1917	1,147,784
1913	855,627	1918	1,776,282

IMPORTS AND EXPORTS.

The value of the imports of grindstones and pulpstones decreased in 1918 to $27,361, which was nearly 53 per cent less than in 1917.

Value of grindstones and pulpstones imported for consumption in the United States, 1913–1918.

1913	$139,386	1915	$68,892	1917	$57,950
1914	109,539	1916	63,277	1918	27,361

The value of the grindstones exported from the United States in 1918 was $210,889, against $198,772 in 1917 and $176,563 in 1916.

CANADIAN PRODUCTION.[1]

The following table, showing quantity and value of grindstones, pulpstones, and scythestones produced in Canada, is inserted for comparison with the production in the United States and because the Canadian output is to some extent contributory to the domestic supply:

Grindstones, pulpstones, and scythestones produced in Canada, 1908–1918.

Year.	Quantity (short tons).	Value.	Year.	Quantity (short tons).	Value.	Year.	Quantity (short tons).	Value.
1908	3,843	$48,128	1912	4,412	$52,090	1916	3,478	$52,782
1909	4,275	54,664	1913	4,837	51,325	1917	2,523	45,754
1910	3,973	47,196	1914	3,976	54,504	1918	3,072	83,005
1911	4,566	52,942	1915	2,508	35,768			

OILSTONES AND SCYTHESTONES.

PRODUCTION.

The value of the oilstones, whetstones, hones, scythestones, and rubbing stones produced in the United States in 1918 amounted to $189,033, an increase of $20,329, or 12 per cent, as compared with 1917, and of $34,460, or 22 per cent, as compared with 1916. The output has not yet risen to the value attained prior to 1914.

Oilstones and whetstones were produced in 1918 from several small quarries, whose product was sold to three manufacturers and reported by them from the Hot Springs district of Garland County, Ark.; by two manufacturers in Orange County, Ind.; and by two in Scioto County, Ohio. Production of scythestones was reported by one company in Huron County, Mich.; one in Grafton County, N. H.; one in Cuyahoga County and one in Scioto County, Ohio; and one in Orleans County, Vt. Rubbing stones were produced by two concerns in Floyd County, Ind. The Kentucky Lithographic Stone Co., at Brandenburg, Meade County, Ky., in 1917 obtained in the course of its quarry operations materials from which it manufactured hones, but it reported none in 1918. Products classified as hones were, however, obtained at Elizabethtown, Hardin County, Ky., by the Kentucky Hone Co.

The greater part of the country's output of the products of this group, as reported to the Geological Survey, consisted of oilstones and whetstones chiefly from Arkansas, and next in importance were scythestones from Vermont, New Hampshire, Ohio, and Michigan. The quantities and values of the several commodities produced in 1918 were as follows: Oilstones and whetstones, 559 short tons, valued at $134,376; scythestones, 6,011 gross (weighing approximately 330 short tons), valued at $37,125; hones and rubbing stones, 240,672 pounds, valued at $17,532. The combined quantity

[1] From reports of Canada Dept. Mines.

was approximately 1,000 short tons. The quantities and values represent products that have for the most part been subjected to finishing and manufacturing processes and are thereby enhanced in value before being sold to consumers, as compared with raw quarry products.

A description of the scythestone industry in New Hampshire was given in this report for 1909, and a description of the Arkansas oilstones, oilstone deposits, and industry was included in the report for 1911.

Value of oilstones and scythestones produced and marketed in the United States, 1909–1918.

1909	[1] $214,019	1913	[1] $207,352	1917	[5] $168,704

1911	[1] 214,991	1915	[4] 115,175		
1912	[1] 232,218	1916	[3] 154,573		

Value of hones, oilstones, and whetstones imported for consumption in the United States, 1913–1918.

1913	$40,222	1915	$14,247	1917	$10,636
1914	33,655	1916	10,614	1918	6,075

CORUNDUM AND EMERY.

SUPPLY.

The sources of the domestic and foreign supply of corundum and emery were briefly summarized in this report for 1917. Little need be added to that statement except that the emery deposits in Pittsylvania County, Va., were successfully exploited during 1918 and yielded a considerable quantity of good material. The better grades of Virginia emery have been tested by use and compare favorably with medium grades of Turkish emery. They are far superior to the emery of Peekskill, N. Y. South African corundum deposits yielded large quantities during 1918 and 1919. This corundum has been found to be of satisfactory grade.

PRODUCTION.

Corundum was produced in 1918 by two operators, one in Macon County and one in Jackson County, N. C.

The domestic emery produced in 1918 came largely from the Peekskill region in Westchester County, N. Y., and from Pittsylvania County, Va. Some emery was also produced in Macon County, N. C. No emery was produced from the mines in Chester, Hampden County, Mass. The production in 1918 was about 10,000 short tons, valued at nearly $75,000 for crude emery f. o. b. mines. This output was 38 per cent smaller than the quantity produced in 1917. The average value of the crude quarry product in 1918 was $7.44 a short ton, a decrease of $3.20, or 30 per cent, as compared with 1917.

---

[a] Estimated. [b] Includes 820 short tons of corundum, valued at $67,461. [c] Includes corundum.

IMPORTS.

The year 1918 was marked by a large increase in the total value of imports of all forms of emery and corundum, amounting to 192 per cent as compared with 1917. The imports have fluctuated irregularly in both quantity and value during the last decade. Because of the war's interference with mining in Turkey and Greece and with shipping the quantity imported in 1917 was far less than in any previous year and probably reached the lowest level.

ABRASIVE GARNET.

PRODUCTION.

The quarry output of domestic garnet sold for use as abrasive material in the United States in 1918 amounted to 4,696 short tons, valued at $248,161. This was a decrease of 299 tons, or 6 per cent,

in quantity and an increase of $49,834, or 25 per cent, in value, as compared with 1917, and a decrease of 1,475 tons, or 24 per cent, in quantity and an increase of $39,311, or 19 per cent, in value, as compared with 1916. Prices ranged from $26.53 to $60 a ton, and the average price was $52.85.

The garnet situation remained unchanged with respect to sources of supply and production in 1919 as compared with 1918. The prices, however, were much higher. They ranged between $50 and $80 a ton, chiefly because of the scarcity of labor, which made it costly to meet the demand. During 1919 a few hundred tons of placer garnet was imported from Almeria, Spain.

Abrasive garnet produced and sold in the United States, 1910–1918.

TRIPOLI, DIATOMACEOUS (INFUSORIAL) EARTH, AND ROTTENSTONE.

PRODUCTION.

Tripoli and diatomaceous (infusorial) earth have been combined for consideration in these reports for many years for the reasons that, because of the confusion in names, it was not expedient to make the separation in the earlier canvasses after the beginning of the production of what is now called tripoli and that the uses of the materials as abrasives are in part the same. Since 1913 the production of diatomaceous earth has also been separately reported, but in the statistics of production the Pennsylvania rottenstone has been included with tripoli.

Diatomaceous earth and tripoli produced and sold in the United States, 1910–1918.

[b] 1916: California, Nevada, and Washington; 1917: California, Nevada, Utah, and Washington; 1918: California, Idaho, Nevada, Utah, and Washington.
[c] 1916: Connecticut, Maryland, Massachusetts, New Hampshire, and New York; 1917: Connecticut, Maryland, and New York; 1918: Connecticut, New York and Virginia.

Production of tripoli and rottenstone.—The tripoli and rottenstone sold for all purposes in the United States in 1918 amounted to 19,982 short tons, valued at $199,854, a decrease of 6,087 tons, or 23 per cent, in quantity, and of $138,334, or 41 per cent, in value, as compared with 1917. The preceding table, giving the tripoli produced and sold in the United States in 1917 and 1918, shows an apparently large difference in price for tripoli as between Illinois and other States. The product in Illinois, Missouri, and Oklahoma was all similar material, valued in the crude state at $1 to $3.50 a ton f. o. b. quarries. The Pennsylvania output, which in the table has been included with that of Missouri and Oklahoma, consisted of rottenstone, which is valued roughly at $15 a short ton. Much of the output in Illinois, Missouri, and Oklahoma was sold ground or, in Missouri, manufactured into filter stones. The prices received for ground tripoli or tripoli flour ranged from $9 to $18 a ton, and the value of filter stones ranged between $18 and $27 a ton.

In Illinois four mines in Alexander County and three in Union County reported the production of tripoli in 1918. The production was 4,129 tons less than that made in 1917, and the estimated average value of the crude material was $1.57 a ton. Most of the output, however, was sold in ground form at prices ranging from $15 to $18 a ton. The total value of the Illinois output at sale prices was $100,126. In Missouri three operators reported production in Newton County,

and one operator in Clinton County produced a small quantity of powdered calcareous shale for use as abrasive material which is included with the output of tripoli in Missouri. A large part of the Missouri-Oklahoma output was made into filter stones, and the scrap from the manufacture of filter stones together with the remainder of the output was ground for sale as tripoli flour. Oklahoma deposits of tripoli were not productive, except one that was worked as part of a plant in Newton County, Mo., and therefore separate data for the two States are not available. The rottenstone produced in Pennsylvania came from Antes Fort, Lycoming County. The total value of the output of tripoli and rottenstone in Missouri, Oklahoma, and Pennsylvania in 1918 at sale prices for crude and finished products was $99,728.

Production of diatomaceous earth.—The diatomaceous earth (also called diatomite, infusorial earth, kieselguhr, tripoli, and tripolite, and sold under various trade names) sold in the United States in 1918 amounted in part to 2,965 short tons, valued at $24,947; in addition, there was a considerable production for special uses, upon which the Geological Survey is not at liberty to report. In 1918 the producing States were California, Connecticut, Idaho, Nevada, New York, Utah, Virginia, and Washington. In the table showing production for 1916, 1917, and 1918, by Western and Eastern States, the product in the Eastern States is valued at two to eight times as much a ton as the western product. The difference is due to the fact that the eastern product was largely sold as high-grade cleaning and polishing preparations, whereas the western product was sold as raw quarry product or went into the manufacture of structural materials and insulation. The projected large developments based on the Maryland and Virginia diatomaceous deposits have not been carried out.

IMPORTS.

1913	$28,696	1915	$27,333	1917	$17,864
1914	20,004	1916	37,573	1918	11,128

PUMICE.

The domestic product sold as pumice prior to 1917 was almost wholly a finely comminuted volcanic dust or "ash" composed of minute fragments of pumiceous, glassy lava, not properly called pumice. This material differs very little from the product made by grinding the imported lump or block pumice and may be substituted for it. Very little lump pumice was obtained from domestic sources prior to 1917. In that year, largely because of the difficulty of shipping from Mediterranean ports, a considerable output of good grades of lump pumice was obtained from the vicinity of Mount Shasta and the Salton Sea in California. Efforts were also made to exploit deposits of lump pumice in Coconino County, Ariz. In May, 1918, an embargo was put on all overseas imports of pumice, so that consumers were forced to depend largely on stocks of Italian pumice remaining in this country and on domestic supplies. Fortunately for the consuming industries, the domestic materials, both volcanic dust from the Great Plains region and the western lump pumice, were

satisfactory for all requirements other than the most exacting, which demand lump of very fine, even texture, free from discrete mineral particles, for lithographic work and for fine finish on copper, silver, and other metals before plating. Probably not more than 100 tons a year of such lump is ordinarily required, and it is possible that these needs might have been met and can again hereafter be met by careful selection from domestic supplies. Furthermore, the situation was relieved because the demand for pumice for finishing work fell off during the war through diminished production in the woodworking industries. This demand has increased since the middle of 1919 and at the end of that year was about the same as before the war. Although there was, during 1919, no restriction on imports, prices for pumice have increased about 10 per cent over prewar prices because of increased ocean freights and increased cost of labor, but even with such increases the cost of imported pumice is less than the cost of domestic pumice. For that reason, and also because the domestic lump is not wholly equal to the Italian pumice for abrasive work and fine finishing work, the California deposits that were opened during the war have been abandoned.

PRODUCTION.

The statistics given represent pumice used for abrasive purposes solely, and those for 1918 include a quantity of lump pumice from California not reported in previous years. The pumice used for building stone and in cement and concrete construction is not included. The material has come from several counties in six States—Humboldt, Inyo, Imperial, and Siskiyou counties, Calif.; Harper, Meade, Morton, and Phillips counties, Kans.; Furnas, Lincoln, and Harlan counties, Nebr.; Custer County, S. Dak.; Cassia and Power counties, Idaho; and Millard County, Utah. Available deposits are very widespread and are particularly abundant in all the Great Plains States from South Dakota to Texas. The Geological Survey received reports of production in 1918 from Humboldt, Imperial, and Siskiyou counties, Calif.; Meade and Harper counties, Kans.; and Furnas and Lincoln counties, Nebr.

The pumice sold or used by these producers in 1918 amounted to 30,637 short tons, valued at $91,178, a decrease of 4,656 tons, or about 13 per cent, in quantity and an increase of $6,364, or 8 per cent, in value, as compared with 1917. In 1918 California produced a small quantity, somewhat larger than in 1916 or 1917. The production in Kansas decreased from that of the preceding year and again far exceeded that from Nebraska, which for a number of years prior to 1916 had been the leading State; and the production in Nebraska was less in 1918 than in 1917.

Pumice produced and sold in the United States, 1910–1918.

PEBBLES FOR GRINDING.

Pebbles used for grinding minerals, ores, cement ingredients and clinker, and other materials may be properly considered abrasive materials. This report prior to 1914 had not included them, because none had been produced in the country except small quantities for local use, of which no record was obtained, and also because the records of imports of foreign pebbles for grinding are not kept separate from those of pebbles that are crushed and used as "flint" in the ceramic industry. The chapters of Mineral Resources on quartz or silica have annually given the quantity of the pebbles imported both for grinding and as flint. Little or no interest had been taken in domestic sources of grinding pebbles until the fall of 1914, when the threatened interruption of imports from Denmark and France, the principal sources of foreign supply, aroused American jobbers and consumers to become independent.

DOMESTIC SUPPLY.

Information on domestic sources of flint or other pebbles used for grinding and of substitutes for such pebbles is summarized in the reports on abrasive materials in Mineral Resources for 1914 and 1916. A recent publication[1] by the Survey describes pebble deposits in Pike, Howard, and Sevier counties, Ark.

In 1918, as in 1917, pebbles for grinding ores, minerals, and clinker were obtained from beaches between Oceanside and Encinitas, San Diego County, Calif. These were gathered and marketed by three or more firms and individuals, whose names and addresses may be obtained from the Geological Survey. These pebbles are gaining in favor in metallurgic and cement plants. Omer Maris, of Manhattan, Nev., continued through 1918 the manufacture of "artificial pebbles" (mechanically smoothed and rounded rock blocks) and supplied metallurgic plants in the vicinity of his plant. The Jasper Stone Co., of Sioux City, Iowa, began a new enterprise during 1917—the manufacture for use as pebbles of 3-inch to 5-inch cubical blocks from the quartzite at its quarry in Rock County, near Jasper, Minn. These cubes are reported to be satisfactory, as they are both very hard and very tough and are said to wear very slowly after the corners and edges are chipped off.

PRODUCTION.

Sales of pebbles, cubes, and artificially rounded blocks for grinding amounted in 1918 to 9,934 short tons, valued at $82,851, a decrease of 17 per cent in quantity as compared with 1917. Besides this marketed output there was a considerable consumption of

[1] Miser, H. D., and Purdue, A. H., Gravel deposits of the Caddo Gap and De Queen quadrangles, Ark.: U. S. Geol. Survey Bull. 690, pp. 15–30, 1918.

substitutes for grinding pebbles by mills that used local pebbles or boulders, lumps of ore, or native rock. The production from all domestic sources in 1919 was far less than in 1918, chiefly because of adverse freight rates, the growing use of steel and iron balls, and a reduction in the quantity of gold and silver ores milled in plants that have used domestic pebbles. Consumers now demand a high degree of roundness and freedom from flaws, which increase the labor cost of producing pebbles. High freight rates have driven some consuming companies to use local material, although such material is generally poor and inefficient.

IMPORTS.

The exact quantity of flint pebbles annually imported for use in grinding is not determinable from reports of the Department of Commerce, as only the total invoice value of imported pebbles of all kinds combined is recorded.

In the accompanying tables are given the value both of "imports for consumption" and of "general imports" classified according to countries of origin.[1] Both groups of figures are of interest to the present discussion.

Value of general imports of pebbles and flint into the United States, 1913–1918.

	1913	1914	1915	1916	1917	1918
Belgium	$10,947	$70,851

1914	432,694		

TUBE-MILL LINING.

"Flint liners" for tube mills are dimension blocks cut from flint or other hard siliceous rock. Before the war almost the entire supply for domestic consumption was imported from Belgium. High prices and the very considerable inconvenience in procuring liners from Europe have developed a domestic supply. During 1918 liners were produced and sold by the American Flint Co., Iron City, Tenn.,

[1] These figures are not identical, because merchandise brought into the country and listed under "general imports" may be put into a warehouse and not be withdrawn for consumption during the calendar year of entry. It is credited "for consumption" to the year of its withdrawal from the warehouse.

and the Jasper Stone Co., Sioux City, Iowa. The output was less than in 1917. Products of these concerns appear to be satisfactory substitutes for the materials formerly imported.

ARTIFICIAL ABRASIVES.

The artificial abrasives here considered are of three kinds—(1) metallic abrasives, manufactured by the Pittsburgh Crushed Steel Co., Pittsburgh, Pa., and including "diamond crushed steel" (crushed crucible steel), "angular grit" (crushed chilled iron), and "crushed cast iron"; (2) silicon carbides, including carborundum, manufactured by the Carborundum Co., at Niagara Falls, N. Y.; crystolon, manufactured by the Norton Co., at Chippewa, Ontario; and carbolon, manufactured by the Exolon Co., at Thorold, Ontario, and Blasdell, N. Y.; (3) aluminum oxides, including alundum, manufactured by the Norton Co., at Niagara Falls, N. Y., and Chippewa, Ontario; aloxite, manufactured by the Carborundum Co., at Niagara Falls, N. Y., Niagara Falls, Ontario, and Shawinigan, Quebec; exolon, manufactured by the Exolon Co., at Blasdell, N. Y., and Thorold, Ontario; lionite, manufactured by the General Abrasives Co. (Inc.), at Niagara Falls, N. Y.; coralox, manufactured by the D. A. Brebner Co. (Ltd.), at Hamilton, Ontario; and natite, manufactured by the National Abrasive Co., at Hamilton, Ontario.

So far as known to the Geological Survey, these are the only artificial abrasives manufactured in North America. Artificial abrasives sold under other names are merely the above-named products marketed under special trade names or are imported products.

In the following table the quantity and value reported for 1918 are incomplete estimates, as certain figures on production during the second half of the year have not been obtained from a producing company.

Artificial abrasives produced in the United States and Canada, 1910–1918.

Year.	Quantity (pounds).	Value.	Year.	Quantity (pounds).	Value.
1910	23,027,000	$1,604,030	1915	37,684,000	$2,248,778
1911	21,292,000	1,493,040	1916	77,612,000	2,935,909
1912	29,002,000	1,747,120	1917	115,822,000	8,137,242

[a] Not including entire production during second half of 1918.

STONE.

By G. F. Loughlin and A. T. Coons.

HISTORICAL REVIEW OF THE STONE INDUSTRY.[1]

The whole country appears to have entered upon a process of general reconstruction in which the mineral industries are involved. Hence it seems appropriate to begin this report with a brief historical review of the changes that have taken place in the stone industry particularly in late years. It must be borne in mind, however, that no previous period is strictly comparable to the present, although the period that followed the Civil War was similar in some respects, and the revival in the building industries beginning about 1896 may fairly be considered as the industrial precursor of the revival that appears to have begun in the fall of 1919.

BEFORE THE CIVIL WAR.

The stone industry in this country, which began with the utilization of boulders and cobbles in Colonial times, was confined almost exclusively to the building and monumental trades for many years. Limestone was quarried for burning lime and for fluxing the small quantity of iron ore then mined, but granite paving blocks were not used until 1840, and the use of crushed stone, though demonstrated by Macadam about 1820, did not make much headway in this country until after the Civil War. Other modern extensive uses of stone, particularly of limestone as a chemical reagent in many manufacturing industries and of dolomite and quartzite for refractory products, were little realized. Ganister bricks from quartzite were first made near Sheffield, England, in 1858–59.[2] This lack of use of stone in the earlier years, including the first quarter of the nineteenth century, was the result, doubtless, of the abundance of timber and brick clay in the present Eastern States. During that period granite cut from boulders in eastern Massachusetts and New Hampshire furnished the principal building stone in those regions. The brown sandstones in Connecticut and probably New Jersey supplied local demands. The light-gray sandstone of Aquia Creek, Va., had gained prominence because of its use in the White House, Capitol, and other buildings in Washington during the very first years of the century and was shipped by water as far as Boston in 1820. This was probably the first stone of more than local importance. It was of a color that would find favor now, but its poor weathering quality brought it into

[1] Abridged in part from a text by Mr. Loughlin, forming a chapter in the "History of the mineral industries," compiled by E. W. Parker for the Carnegie Institution.
[2] Quarry, July, 1919, p. 184.

disrepute and it has not been quarried to any extent since 1840. The stone still in use has been preserved from further weathering by painting its surface. Marble quarried in Vermont, Massachusetts, Pennsylvania, and Maryland was used for tombstones, sills, steps, and a few monuments during the early part of the century, but no marble-faced building was erected until 1854. Limestone and sandstone were also used locally for buildings and tombstones in New York, Pennsylvania, Maryland, and States farther west. The oolitic limestone of Indiana found local use as early as 1819.

During the second quarter of the century quarries were opened in several States and Territories, even as far west as California, and the building-stone industry made marked progress. Systematic granite quarrying began in 1825, largely as a result of improved methods of quarrying and handling large blocks at Quincy, Mass., for the erection of Bunker Hill Monument, and this led to the construction of many granite buildings in Boston, New York, Philadelphia, and other cities. The Quincy granite, owing, no doubt, to its reputation gained as the stone used in Bunker Hill Monument, to its favorable position near tidewater, and to the more advanced methods of quarrying it, was probably the leading building granite during this period, although other granites, quarried along the coast of Maine and Massachusetts, were finding an equally extensive range of markets. Other New England granites, now well known, were supplying mostly local demands, which included a few important buildings, such as the State capitols of New Hampshire and Vermont.

The marble industry continued to develop slowly during the second quarter of the century, furnishing principally tombstones. Limestones and most sandstones continued to supply local demands, but the brownstones attained national prominence and the famous brownstone fronts had begun their invasion of New York.

Toward the middle of the century railroads attained a considerable growth and began to afford a means whereby stones of superior architectural merit were admitted to hitherto inaccessible markets. Thus Vermont and Massachusetts marbles displaced the marble of Montgomery County, Pa., as early as 1840, and the gray and buff sandstones of northern Ohio made their appearance in New York in 1857, beginning to compete with the brownstones of Connecticut and New Jersey and with the brown and white sandstones of Medina, N. Y., which had previously been shipped by water to cities in Ohio and Michigan.

Street paving was done with cobblestones from Colonial times until about 1850. Granite paving blocks were introduced into Boston in 1840, into Philadelphia in 1848, and into New York about 1850. The blocks first used were considerably larger than the modern blocks, their surfaces measuring a square foot or more in area; but repeated experience soon resulted in the adoption of blocks essentially like those used to-day.[3]

The date when flagstones for sidewalks and crossings were introduced is not definitely known, but it was probably early in the nineteenth century, as the mica schist quarries of Bolton and Vernon, Conn., had already been considerably developed by 1837. This stone was not well situated for economical quarrying, and it may have been

[3] Braley, A. W., History of the granite industry of New England, vol. 1, pp. 167—170, Boston, 1913.

this fact as well as the softness of the stone compared with granite and the well-known Hudson River flagstones that caused these quarries to be abandoned long ago, perhaps before the Civil War. This mica schist was used extensively in Hartford, Conn., 12 miles from the quarries, and to some extent in Boston, and perhaps in New York and elsewhere. It is still to be seen in Hartford. The Hudson River bluestone was probably quarried as early as 1840 in Ulster County, N. Y. Granite flaggings, principally from Quincy and Rockport, Mass., were probably introduced before the Civil War, and flaggings from granite quarries along the coast of Maine were probably used in Boston and other cities along the Atlantic coast not long afterward.

The stone quarries had increased considerably in number by 1860 but still supplied chiefly a local demand. The only other noteworthy feature was a marked growth of the Vermont marble industry between 1850 and 1860, and the use of marble for the facing of buildings as well as for trimmings and tombstones. The brownstones reached the culmination of their popularity in New York from 1840 to 1860, though they were used extensively for some time afterward.

According to the Seventh and Eighth Census reports, stone produced at the leading quarries was valued at $8,180,115 in 1850, and at only $4,265,899 in 1860. This apparent decline of nearly 50 per cent may have been due in part to failure to obtain returns from many important producers and in part to unsettled conditions just before the Civil War. The difference may also have been due in part to the inclusion of figures from stone-cutting plants in 1850. The total value of the output reported from such plants in 1860 was $16,244,044. Quarry production in 1860 was reported from only 18 States, as follows:

Principal stone-producing States in 1860.

State.	Value of product (eighth census).	Principal kinds of stone.
Vermont	$715,550	All marble.
New York	647,357	Sandstone, limestone, granite (gneiss).
New Jersey	580,727	Brownstone.
Connecticut	532,704	Sandstone mostly, some granite.
Pennsylvania	418,591	Gneiss, sandstone, serpentine, and limestone.
Maryland	346,900	Marble ($300,000), brownstone, granite.
Maine	295,280	Granite.
Massachusetts	289,626	Granite, marble ($122,496), "puddingstone."
Missouri	230,376	Limestone, sandstone(?).
Illinois	64,148	Limestone, sandstone.
Ohio	63,600	Sandstone, limestone.
Indiana	37,800	Limestone.
New Hampshire	23,540	Granite.
Rhode Island	6,800	Granite.
Michigan	6,550	Sandstone, limestone.
Wisconsin	3,800	Sandstone, limestone (granite?).
Delaware	2,000	Granite, gabbro-diorite.
Iowa	550	Gypsum, limestone.
	4,265,899	

Of the total value, $1,863,500, or 44 per cent, was from the New England States; $1,995,575, or 47 per cent, from the Middle Atlantic States; and $406,824, or 9 per cent, from the "Western States," only two of which were west of Mississippi River.

These figures, though doubtless incomplete, show some interesting contrasts not only in values of output from the present important States, but in the relative value of different kinds of stone. Vermont, then as now, was the leading State in the production of marble, which was used for both monumental and building work, but produced no granite of more than local importance. The production of marble in Massachusetts and Maryland was relatively more important then than in recent years and exceeded their outputs in 1917 and 1918. Production from several marble quarries in Massachusetts and Connecticut, as well as Pennsylvania, had already declined or ceased, owing to the growing popularity of Vermont marble as well as marble imported from Italy. Marble then supplied about all the demand for monumental stone, granite being little used for this purpose until after 1860. New Jersey and Connecticut owed their prominence to brownstone, whereas in 1917 the value of the output of sandstone in New Jersey was less than $7,000, and the output in Connecticut has also greatly declined. The granite industry in Maine and Massachusetts was considered very prosperous then, although its value was only a small fraction of the present value. It is regretted that figures showing quantities of stone produced are not available, as the figures for 1860 were based on conditions just before or during the early stages of an advance in prices whereas the figures for 1917 and 1918 are based on prices existing approximately at the culmination of a period of high prices. Granite quarrying in New Hampshire was still a local industry. Ohio, which in the eighties advanced to the lead in value of stone, chiefly sandstone, was a minor State in 1860. Sandstone from Buena Vista, quarried largely for the Cincinnati market, was then well known, but the famous gray and buff sandstones of Amherst and Berea were only in the early stages of development. Indiana represents a similar but more striking contrast. Its oolitic limestone, though worked for local use from the first decade of the century, was not destined to attain national importance until about 1880.

SINCE THE CIVIL WAR.

SCARCITY OF INFORMATION BEFORE 1880.

There are no data available to show the effect of the Civil War upon the stone industry, and none of much value for showing the size and growth of the industry before 1880. The Ninth Census report gives a total value of $10,775,400 for the output in 1870 from the larger quarries but states that no account was taken of quarries worked irregularly and for local purposes only and admits that many important quarries were undoubtedly overlooked.[3] The value recorded for marble in 1870 was only $804,300, whereas that of granite, sandstone, and limestone together had risen to $9,971,100. The figures may show a substantial increase in total value of the output of the leading quarries compared with the period before the Civil War, but the comparative condition of the industry is obscured by the fact that prices were relatively high in 1870. Wars which took place between 1855 and 1870 had the combined effect of increasing the

[3] Ninth Census, vol. 3, p. 749, 1872.

public debt, especially in France and the United States. There was a prolonged rise in prices which culminated in 1864 but which persisted at least until 1880. The severe financial panic of 1873 had little effect on checking the high prices.[4]

During the 25 years following the Civil War the stones that were most prominent before the war still led in production. Brownstone, which had found a comparatively very small use in Boston before the war, began in 1865 to supply a great demand, which lasted in that city for about 20 years and, though declining, was important until about 1900. The demand evidently continued to be important in other large eastern cities, although the decline was apparent in New York at an earlier date than in Boston.

The New England granites continued to supply the larger building markets, particularly for heavy masonry, but by 1880 their adaptability for monumental work had become generally appreciated. Marble, chiefly from Vermont, continued to supply the bulk of the monumental trade, however, and was also used for many building fronts, particularly in the seventies. Gray sandstone and limestone continued to be mainly of local importance. The advantage of water transportation and, to a less extent, proximity to large markets appeared still to be dominant factors in the quarry industry.

BUILDING STONE.

1865–1890.—Many of the building stones that were most prominent during the first 20 or 25 years after the Civil War were comparatively dark in color. The brownstones, the Quincy granite, and the darker-red granites of Maine were notable examples, whereas the gray granite of Rockport, Mass., and the lighter-gray granites of Hallowell, Maine, and Concord, N. H., represented the more prominent stones of lighter color. The lighter-pink coarse-grained granites had been regarded with less favor by some because of their texture and because their minerals lacked sufficient contrast in color, especially for monumental work.[5] During the seventies, however, the use of the Indiana oolitic limestone in local important buildings had begun to attract favorable attention. Toward the end of that decade it was used in the construction of the Chicago City Hall and was also introduced into New York. During the next 10 years it was used in the construction of several prominent buildings in New York and doubtless in other important cities in the Central and Middle Atlantic States. By 1890 or 1895 it had been used as far east as Boston, Mass., as far south as Tallahassee, Fla., and as far west as Duluth, Minn; Topeka, Kans.; and El Paso, Tex.[6] A monument base of it had been exported to Caracas, Venezuela.

The ease and cheapness of quarrying and finishing this stone allowed it to compete in spite of long railroad hauls with the more favorably situated and heretofore most prominent building stones, and this all-important fact, together with the relief and contrast which its light-buff and gray colors gave from the more somber

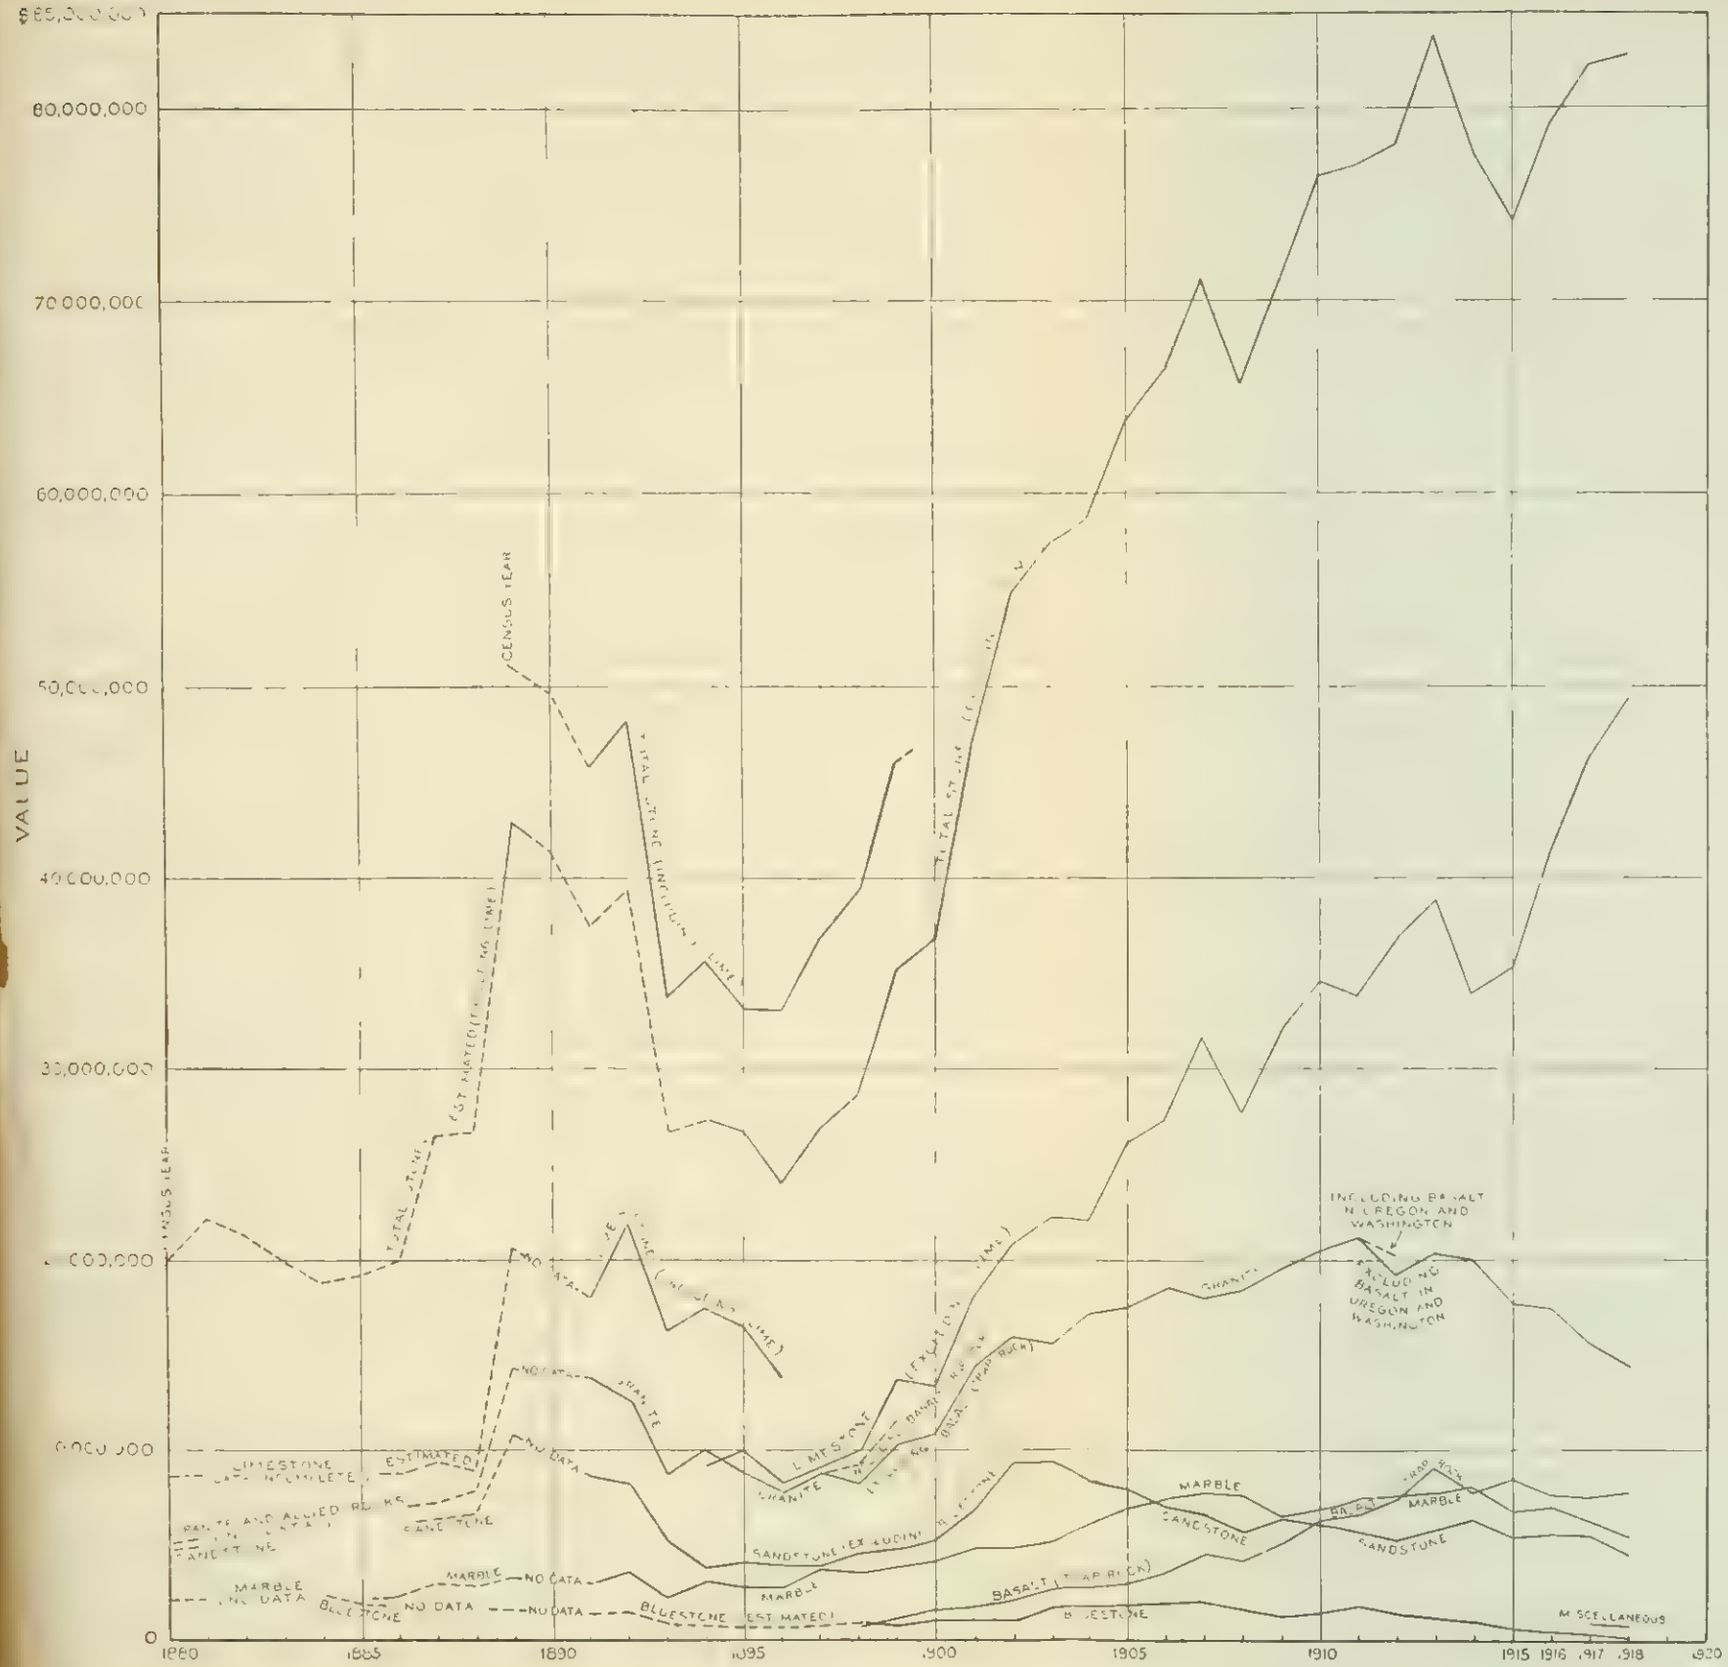
brownstones and red granites, was a great aid in bringing about a change in fashion favoring light-colored stone for building. This change was also beneficial to the light-buff and gray sandstones of northern Ohio, and to the pale-pink granites, particularly of the Penobscot Bay district, Maine, and Milford, Mass., which gained prominence in 1895–1900, as well as to the already prominent light-gray granites.

During the period from 1865 to 1890 building stone was undoubtedly the leading stone product, although no separate statistics of the value of stone products were compiled until 1898. Monumental and perhaps paving stone were prominent. Crushed stone and limestone for flux were also important products, though insignificant compared with their present prominence, and the Portland cement industry, which had been little more than a curiosity, had just begun to show an increased production in 1890.

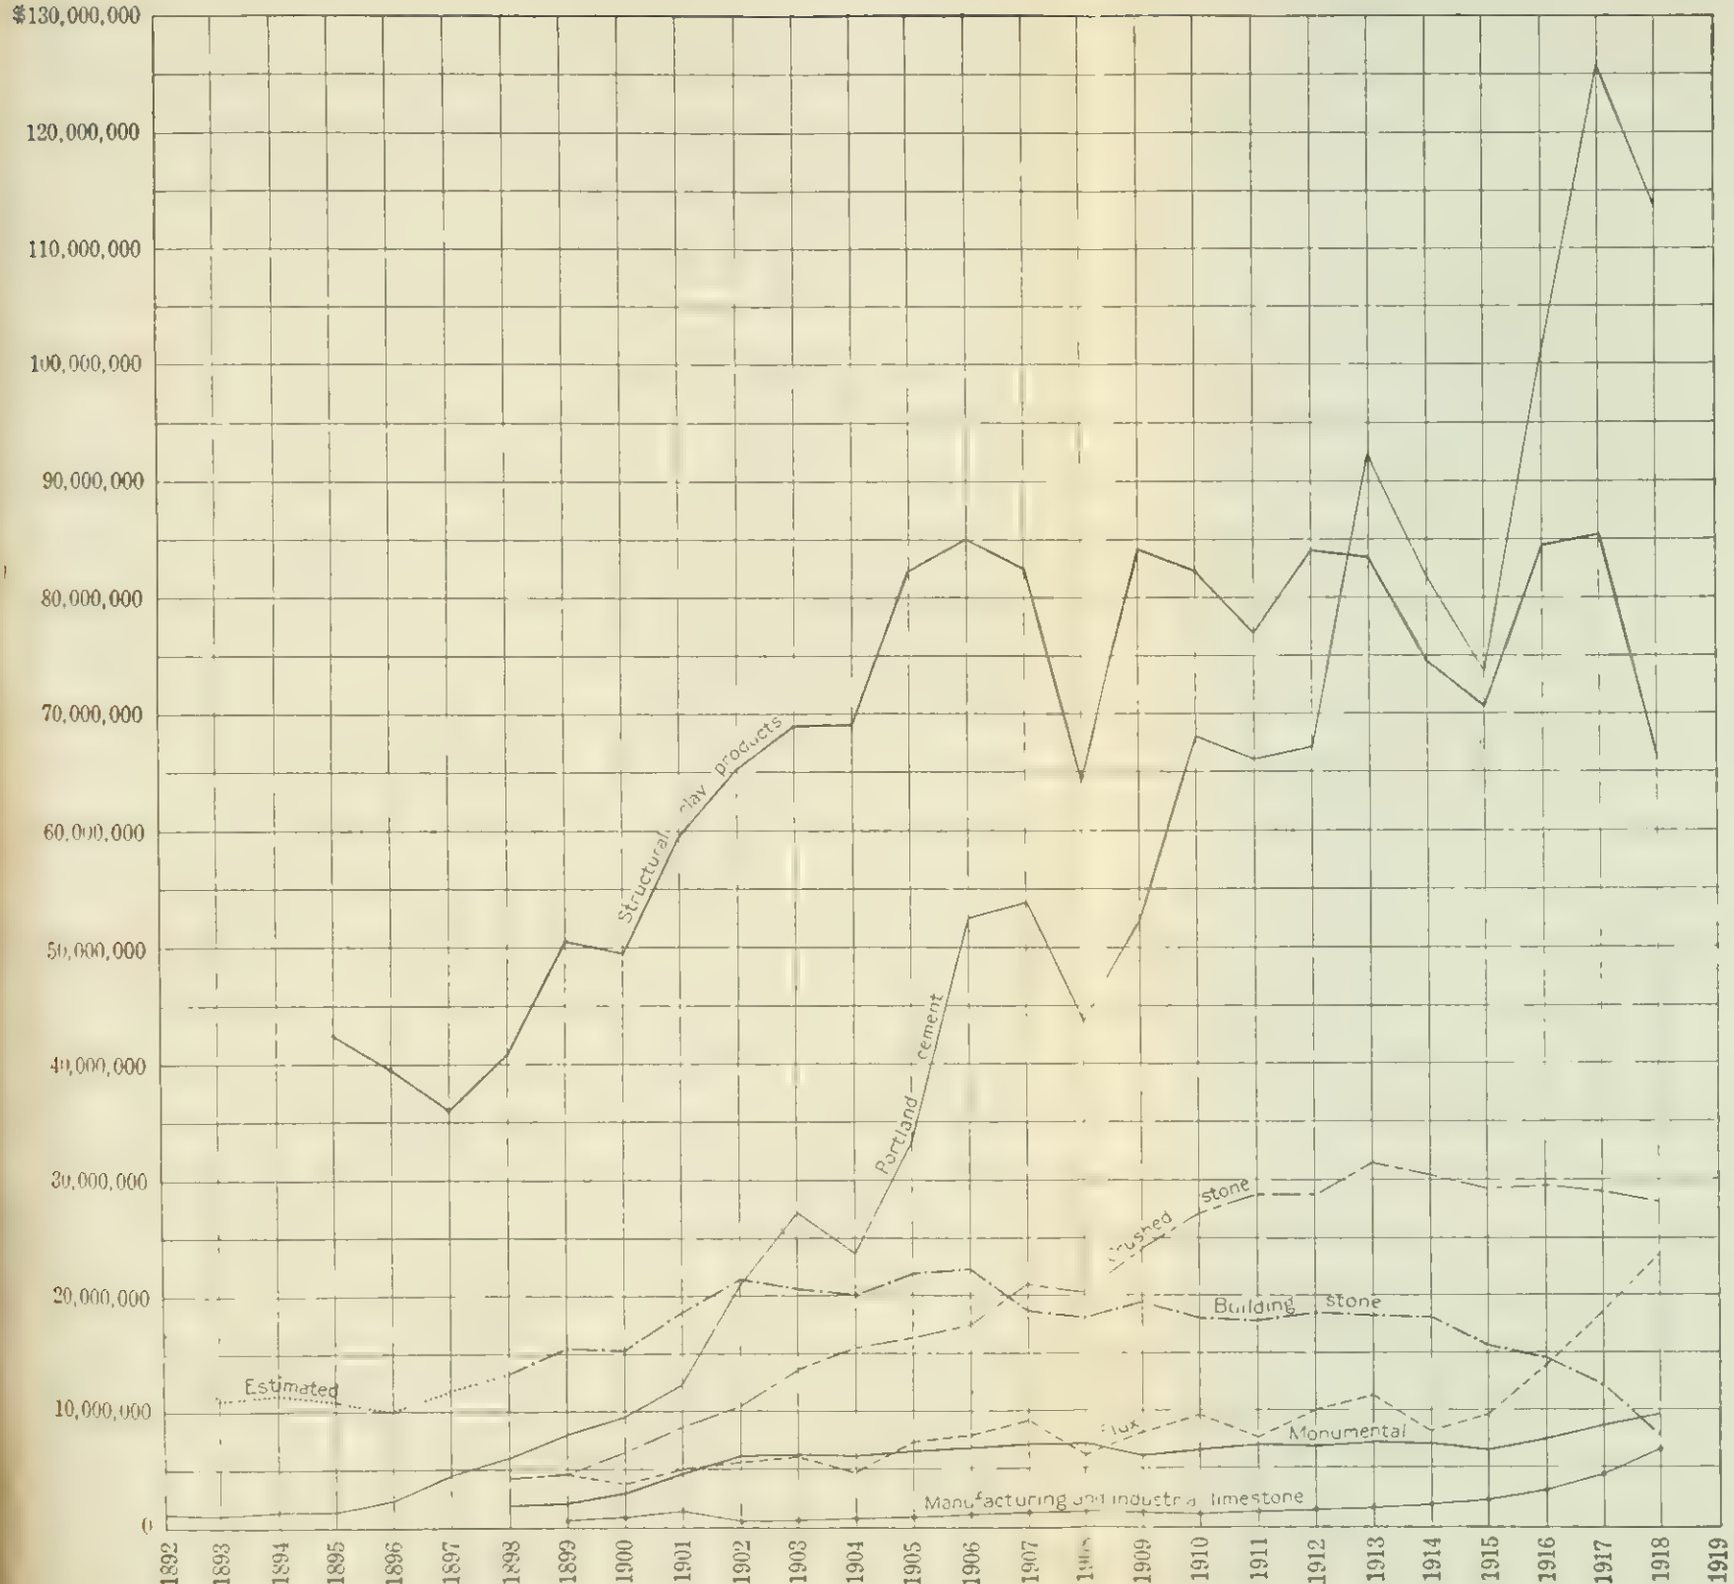
Lack of even approximate statistical data renders it impossible to show the effect of business conditions upon the stone industry before 1880. The panic of 1873 doubtless caused a general curtailment of building, and a depression in the building industry is said to have existed from 1876 to 1880.

Approximate annual statistics of production began to be collected in 1880. According to the Tenth Census report, the total value of stone produced in 1880 was about $20,000,000, nearly double the incomplete figure for 1870. (See Pl. IX.) Granite and sandstone produced in 1880 were valued at about $5,000,000; limestone, exclusive of that burned into lime, probably had a similar value, and marble less than half as much. Statistical reports based on very incomplete information were begun by the newly organized United States Geological Survey in 1882. Although building activity increased in 1883, the total value of stone sold was thought to have decreased because of a marked preference for brick construction. To this preference and another general industrial decline was attributed a further decrease in 1884. In 1885 granite and some harder varieties of sandstone increased slightly in favor, whereas the brownstones continued their general decline. In 1886, despite labor troubles, the quantity of stone produced was greater, but prices were lower, owing to such causes as increase in competition, the introduction of new kinds of stone, and efforts to establish markets in new localities. The popularity of granite for ornamental and decorative uses was increasing markedly, the marbles of Tennessee and Georgia had already attained a considerable and growing reputation, and Ohio had become the leading producer of sandstone. During the next three years, or until 1890, the stone industry was generally prosperous, and the period 1886–1890 was the first of two conspicuously prosperous periods for the building-stone industry since annual statistical information has been available.

The apparent great increase in value of stone produced in 1889 over previous years, as recorded by the Tenth Census was evidently the result of a much more complete canvass of the industry and probably to the inclusion of some manufacturing plants with quarries. Several other well-known stones obtained recognition during this period, and so far as quarry districts and range of markets were concerned the stone industry was about as extensive as it is to-day.



VALUE OF STONE SOLD IN THE UNITED STATES, 1880–1918.



VALUE OF PORTLAND CEMENT, STRUCTURAL CLAY PRODUCTS, AND THE MORE IMPORTANT STONE PRODUCTS SOLD IN THE UNITED STATES, 1892-1918

1891–1918.—This period of prosperity induced overproduction, especially of limestone, and was ended by a decline in the demand for buildings in the larger cities in 1891. Labor troubles in 1891 and 1892 further curtailed production. These dull years were followed by the panic of 1893, when the values of both stone and structural clay products decreased greatly. The value of stone decreased 30 per cent and continued on the whole to decline until 1896 (Pl. IX), whereas the value of structural clay products declined until 1897 (Pl. X). Judged by the length of this period of depression and by the fact that building stone was still by far the leading stone product, the building industry was among the first to suffer and the last to recover. The total value of building stone sold in 1896 was estimated at about $10,000,000.

Portland cement, which had been of almost negligible importance up to 1890, then began to increase rapidly in production, and in 1897 its value exceeded the combined value of marble and bluestone and was about equal to that of all other kinds of sandstone. Its production was not curtailed during the period of depression, and decreasing costs of its manufacture accelerated its marketed production.

The demand for buildings of all kinds had by this time so far exceeded the supply that the value of the building stone, structural clay products, and Portland cement sold increased rapidly until 1903. In that year the value of building stone declined somewhat and was passed by that of Portland cement. In 1904 both building stone and cement decreased in value, while structural clay products held their own. In 1905 and 1906 all three products again increased, but exterior building stone did not quite attain its record value ($20,790,341) of 1902, whereas both clay products and cement far surpassed their previous records. Total building stone, including interior marble, attained its record value, however, in 1906. In 1907 and 1908 a period of depression less severe than that of 1903, the three products again declined, although not uniformly, presumably owing to irregularity in completion of contracts. They all gained in 1909, but the gain in building stone was very small in comparison to those of the others. Since 1909 building stone has almost continuously declined in total value, and the decline has been especially marked since 1912. Structural clay products have fluctuated since 1906 but on the whole declined in value until 1916, and in 1913 they were passed by Portland cement, which has led in value since then. The year 1916 was one of great building activity, as is reflected by the gains in value of structural clay products and Portland cement, but the great majority of the buildings erected were not of the kind that calls for stone.

Since the country entered the World War in 1917 all classes of building have been curtailed and all three materials—building stone, structural clay products, and Portland cement—have decreased markedly in quantity, although the great increase in prices has maintained the respective values at relatively high levels. In spite of increase in selling price, however, the total values of exterior building stones in 1915 and later years are lower than any recorded by the Geological Survey before that date, and it is possible that the values for 1917 and 1918 are the lowest since 1880. It is unfortunate that figures showing the quantity sold annually over a

long period of years are not available for stone and clay products as they are for cement, because they would show the actual changes in rate of consumption, but fluctations in price have not been, for the most part, sufficiently great to render the accompanying diagrams very misleading, except in respect to 1917 and 1918.

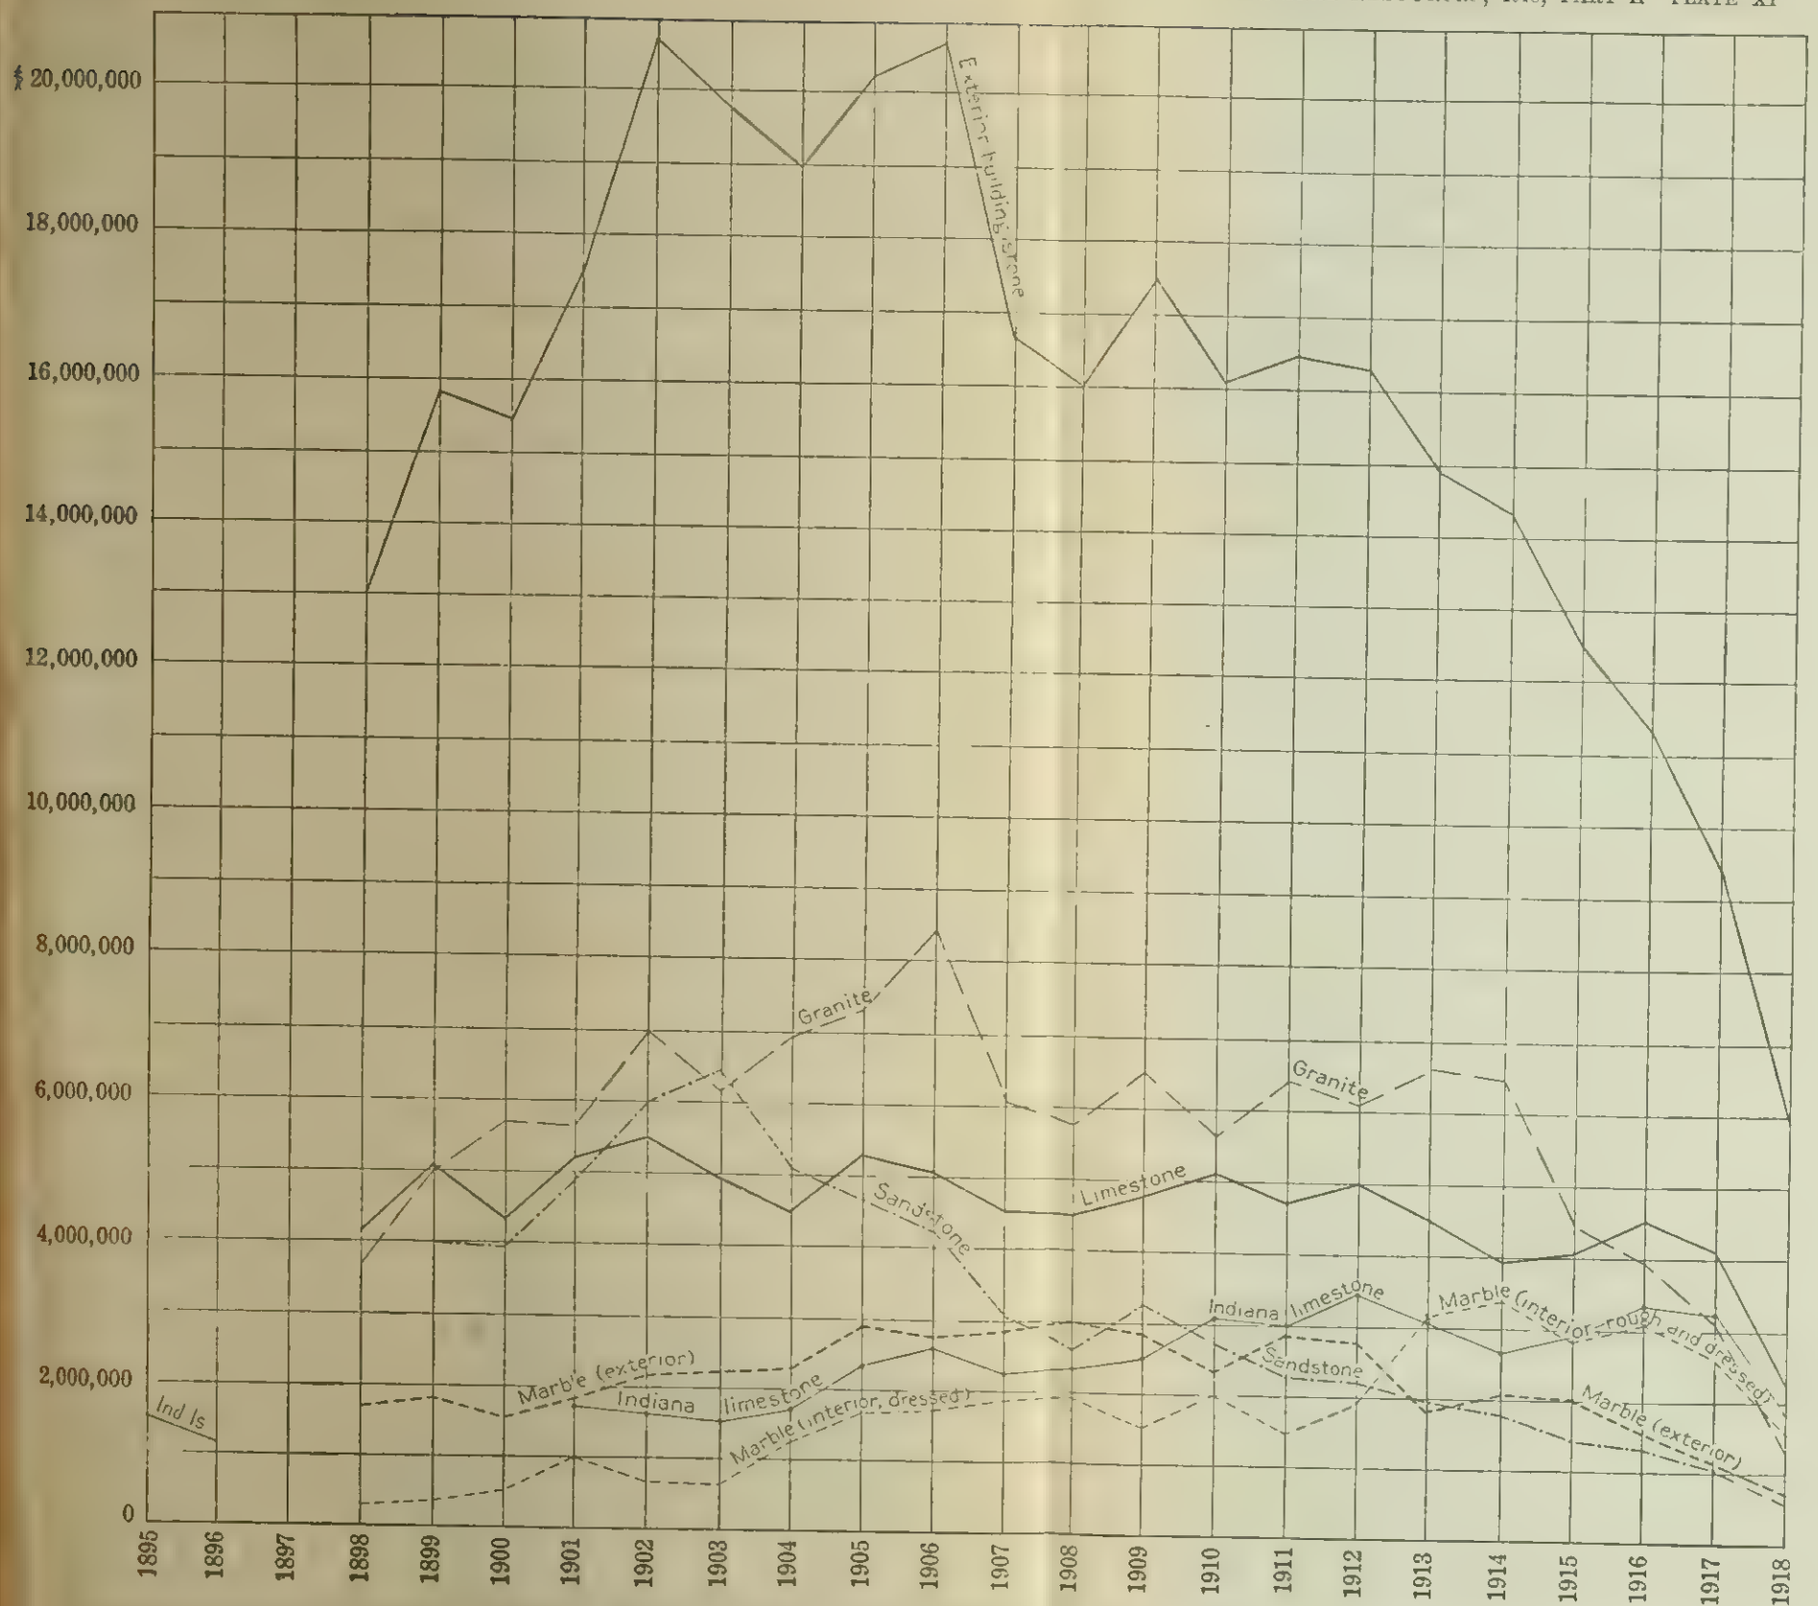
Detailed statistics, 1898–1918.—Plate XI traces the changes in value of granite, marble, limestone, and sandstone sold for building since 1898, the first year in which figures for building stone could be accurately separated from those of other kinds. It was not until 1907, when the period of general decline in total value of building stone began, that any figures for quantity of building stone sold could be published. Figure 110 represents the changes in quantity sold in different districts and groups of districts so far as figures are available.

All kinds of building stone increased in value on the whole from 1898 to 1902, but it is interesting to note that Indiana limestone decreased in value in 1902, when the maximum total value was reached. Granite and marble continued this general increase until 1906, and Indiana limestone also increased in value from 1903 to 1906; but total limestone showed a slight net decline, and sandstone, after gaining in 1903, decreased more than $2,000,000 in the next three years. Since 1906 sandstone and total limestone have undergone general declines in value, although Indiana limestone showed a net gain until 1912. Marble for exterior building fluctuated, but on the whole held its own until 1912. Granite, after a severe decline in 1907, fluctuated, but made a slight net gain until 1913. Since 1914, granite, marble, and sandstone have declined, whereas limestone, three-quarters of whose value was represented by Indiana limestone, gained during 1915 and 1916, after which natural and forced curtailments of building brought a severe decline in the value of all kinds of building stone.

As changes in price during the years preceding 1916 were not abrupt the curves representing values in Plate XI give a fair general idea of the trend of the industry.

Figure 110 shows strikingly the great preponderance in quantity of Indiana limestone sold annually and its marked increase from 1907 to 1912. Its decline since then has been generally paralleled by granite and marble. Building granite in Vermont fluctuated, owing largely to the beginning or completion of large contracts, but on the whole increased from 1907 until 1913, its quantity curve for these years roughly paralleling the corresponding part of the value curve for total granite.

Causes of recent decline.—The period from 1902 to the present has been marked by changes in the building industry that have given Portland cement the advantage over building stone and structural clay products. There was on the whole plenty of building activity, but the trend of architectural style and methods of architectural and engineering construction were powerfully affected by the use of cement and concrete. In the immediate future conditions may closely resemble those that existed after the severe depression between 1890 and 1896. There is a shortage of buildings of all kinds, and there should therefore be a strong demand for all of the three building materials. How long this period of strong demand will last can



VALUE OF EXTERIOR BUILDING STONE AND OF GRANITE, MARBLE, LIMESTONE, AND SANDSTONE SOLD FOR BUILDING IN THE UNITED STATES, 1898-1918.

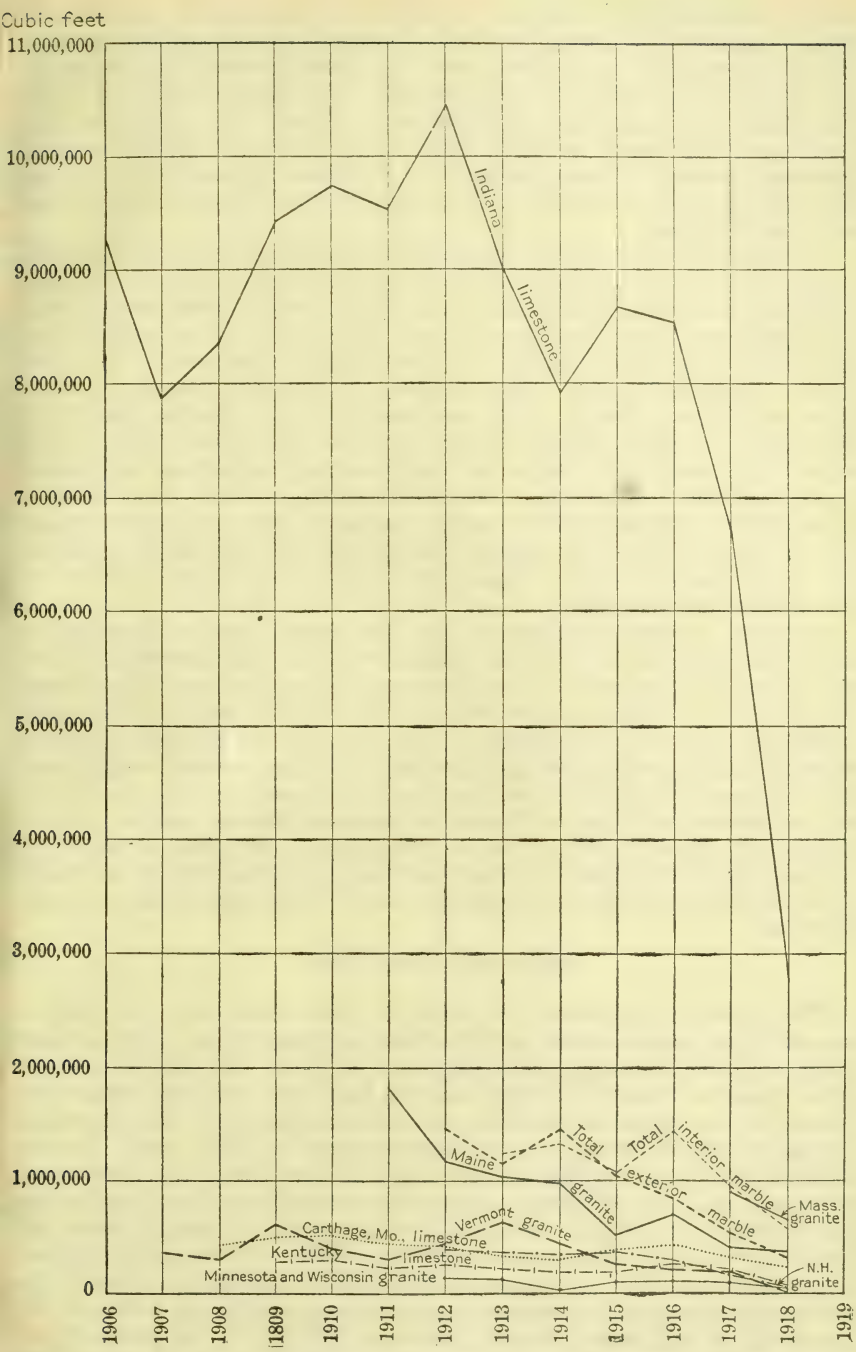


FIGURE 110.—Quantities of certain more important building stones sold in the United States, 1906–1918, by districts.

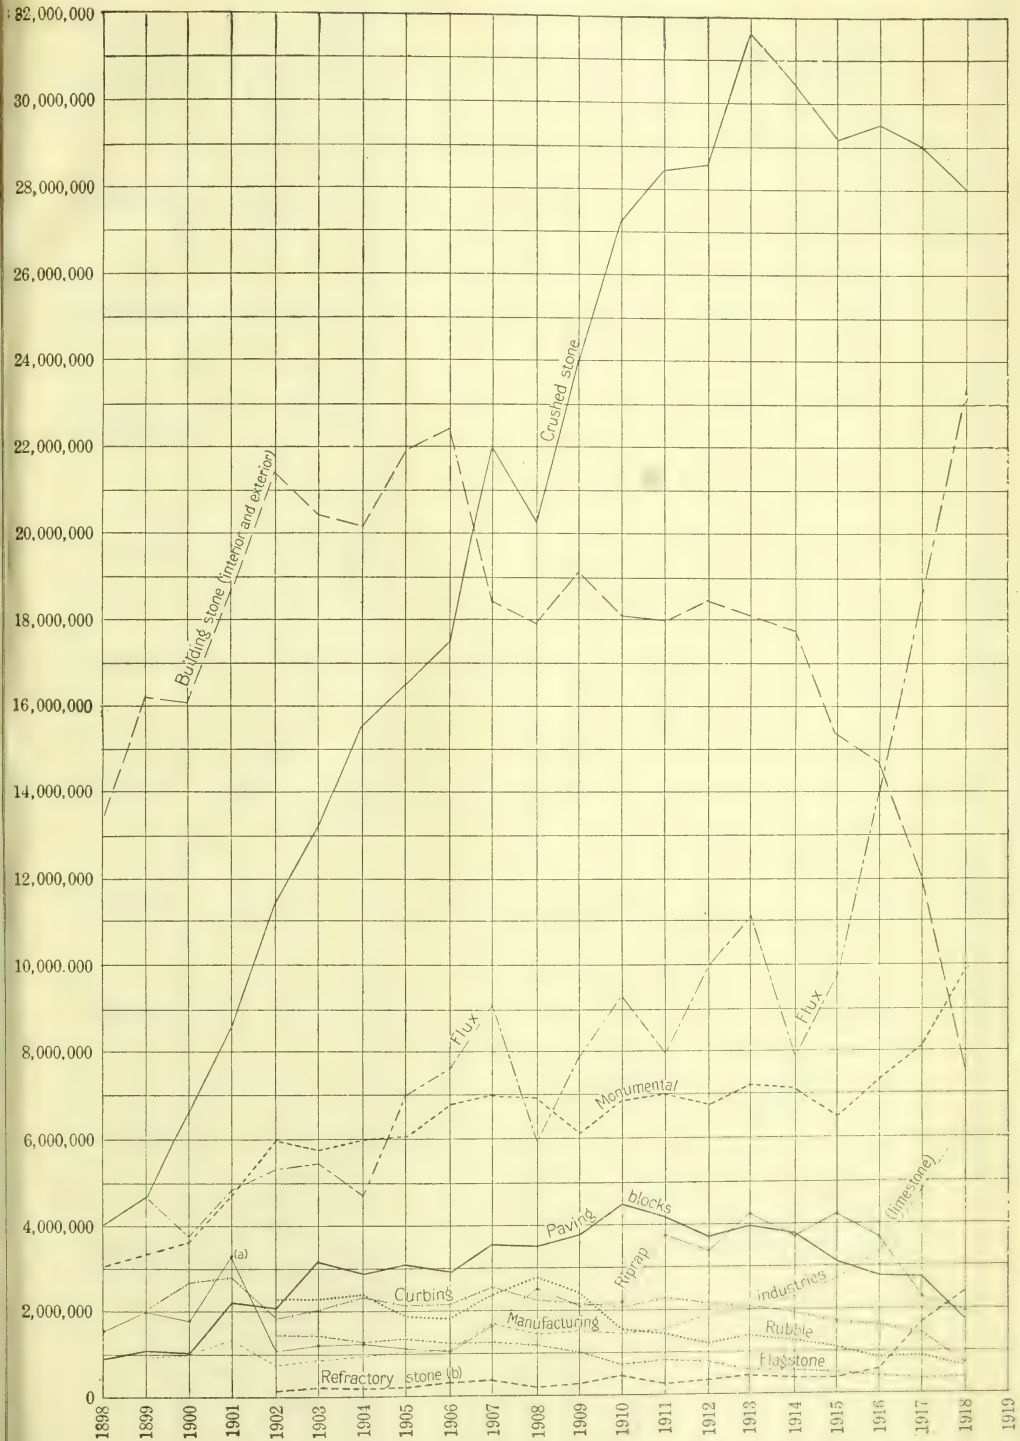
not be foretold, and statistics showing the increase in quantity of these products sold during periods of normal growth of the country are too incomplete to indicate how far below normal the consumption of building materials is at present. As regards building stone, there has been a shortage of high-class building since 1913, and this shortage of six years' duration must be compensated while a normal growing demand is being supplied. Informal opinions by men in close touch with the situation forecast a strong demand for the next seven to ten years.

A striking feature of the building-stone industry until the last few years was the lack of cooperation among producers. Because of this, building stone had doubtless suffered more severely from competition with the better-organized cement and clay-products industries than its true qualities and relative cost should have permitted. This was in part remedied by the organization of local and general associations, which had already done considerable to put the building-stone industry on a more modern basis; but their efforts were only begun when war conditions placed all the building industries, organized and unorganized alike, in a most unfortunate position. Now that the demand for buildings of the better classes is due to revive, cooperation on the part of these associations to see that the merits of stone are fairly judged should regain for the stone industry its share of the building construction.

Outlook.—When the demand for war uses caused a shortage in structural steel there was some hope that the building-stone industry would benefit by a return to solid masonry construction. The forced curtailment of building, however, and the short duration of the participation by the United States in the war did not give the required opportunity for such a change in methods of construction to take place. Stone, therefore, is likely to continue to be used mainly for facing and trimming buildings with steel or concrete frames, and its increase in use will depend on its cost of production, its relative merits in competition with other building materials, and the extent to which architectural style in both large and small buildings trends in favor of stone.

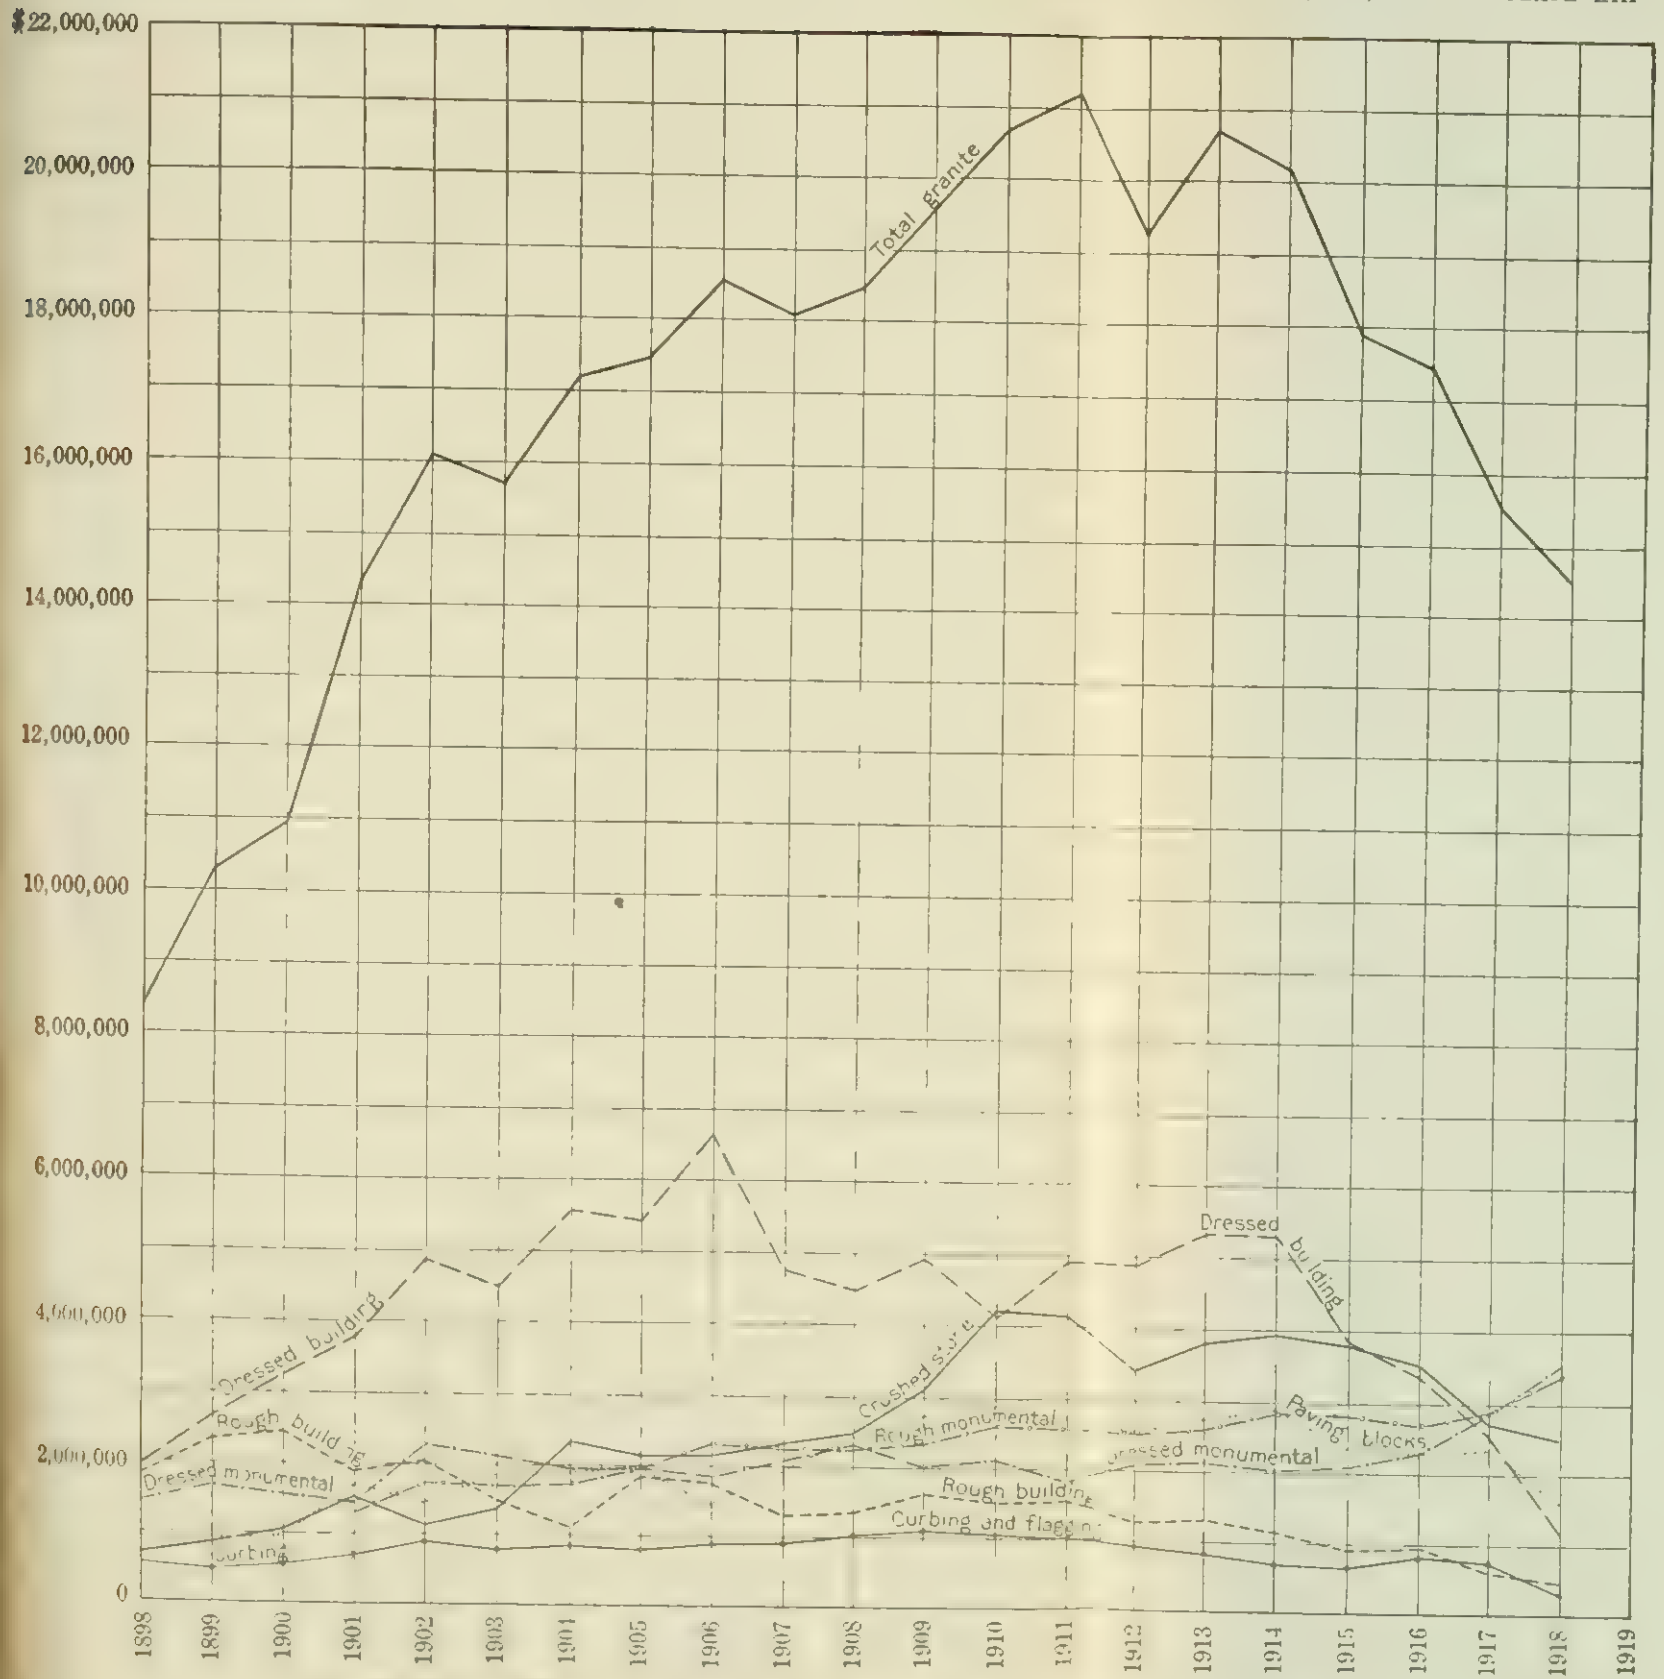
STONE FOR OTHER USES.

The growing importance of stone for uses other than building is shown by an examination of the accompanying plates. Comparison of the curves for exterior building stone in Plate XI with curves for total stone in Plate IX brings out the fact that building stone continued to be the principal stone product during both the depressed period of 1892–1896 and the prosperous period of 1897–1902. During most of these years it represented about 40 per cent of the total value of stone sold. Since 1900, however, its proportion of the total value has become less and less. In 1907 it was passed by crushed stone and in 1917 by furnace flux, as shown in Plate XII. The general increase in granite since 1907, as shown in Plate XIII, reflects principally the growing importance of crushed stone, monumental stone, and to a less extent of paving stone; that of limestone (Pl. XV), the growing importance of furnace flux, crushed stone, and stone for chemical and refractory use. Sandstone, a greater portion of which was used for building than for other purposes before the war, most nearly parallels



VALUE OF STONE PRODUCTS SOLD IN THE UNITED STATES, 1898–1918, ACCORDING TO USES.

(a) Includes rubble; (b) 1902–1916, mica schist and ganister; 1917–1918, mica schist, ganister, and dolomite.



VALUE OF GRANITE SOLD IN THE UNITED STATES, 1898-1918, ACCORDING TO USES.

the declining building-stone curve, and its diversion from this course since 1914 is due to the increasing use of certain varieties of sandstone (principally quartzite) for refractory purposes. Marble has, on the whole, maintained a uniform value, because of its importance in monumental work and in the interior finish of many buildings that contain little or no exterior building stone. The general increase in value of interior marble until 1914 and its minor importance compared with total exterior stone are shown in Plate XI.

The stone industry has thus evolved during the last two decades into a more varied industry than formerly and has been marked by the decline of building stone and certain closely related products and the rise of other products, as shown in Plate XII. This evolution has been gradual and is still in progress, but the transition from the simple to the complex may be said to have taken place between 1890 and 1900. Other uses of stone than building and monumental, though known many years before 1890, did not attract much general attention until then. This statement applies particularly to crushed stone, the use of which had begun prior to 1880, but which was not considered a sufficiently important product to receive more than passing notice. Interpolation from the curves in Plates IX and XII, however, indicates that its total value in 1890 was probably not much in excess of $1,000,000, whereas statistics for 1900 show a value of more than $6,000,000. The earliest definite figures, those for 1898, show a value not much less than that of cement. In the preceding years it was used mainly for road metal, but concrete aggregate and railroad ballast were becoming increasingly important. The steady increase in value of crushed stone until 1914 is in general accord with the nearly steady increase in value of Portland cement, and further illustrates the rapid growth of concrete construction as well as the activity in the improvement of roads. The competition of gravel in concrete and road work has been marked in recent years, but this has been only a minor cause of the gradual decline in value since 1913, which has been due mainly to curtailment first in road and railroad building and, during 1917 and 1918, in concrete building as well.

General parallelism between the crushed-stone curve in Plate XII and the limestone curve since 1898 in Plate IX indicates that limestone has been the principal variety of crushed stone. The excess of the value of limestone over that of total crushed stone, however, is due largely to the value of furnace flux. This product has rapidly increased in importance, keeping pace with the marked growth of the iron and steel and smelting industries, until during the war it became the leading limestone product. The importance of steel in construction work of all kinds, which has increased so markedly since 1896, accounts for the contemporaneous growth in production of flux and to some extent of crushed stone. Decrease in the tenor of iron ore has also tended to increase the quantity of limestone quarried for flux, and the growing demand for limestone very low in harmful impurities has tended to increase the quality as well as the price of stone for this purpose.

Recognition of the importance of limestone in those manufacturing industries using chemical processes has brought about a remarkable increase in the value of stone for various chemical uses in the last few years, as shown in Plate XII. The marked increase in value of

stone for refractories during recent years also illustrates the growing importance of stone as an accessory to certain manufacturing industries, particularly the steel and by-product coke industries.

Monumental stone has maintained its importance in spite of advances in price, as it is favored by a steady demand little affected by general industrial conditions. During the war it has become the most valuable product of granite and marble quarries, and several companies whose main product has been building stone are now turning their attention to monumental stone.

Paving stone has been for years competing with other paving materials, which had certain advantages over stone as formerly prepared and laid, and has undergone a general decline in value since 1910. There is no question regarding the greater resistance to wear of granite, diabase, basalt, and quartzite paving blocks, and the latest improved methods of preparing and laying them produce smooth road surfaces that will maintain their smoothness so long as the foundation upon which the blocks rest withstands the weight of traffic. As cheaper pavements are proving generally satisfactory for light to rather heavy traffic, the growth of the paving-block industry should keep pace with the growth of extremely heavy city traffic and in the next few years should make up for the curtailment in street improvements during the war.

Riprap and rubble will doubtless continue to fluctuate in production as they have in the past. Where abundant local supplies render them the most economical material for certain structural work they will find temporary use, but they can never be expected to supply more than local demands.

SUMMARY.

The foregoing discussion may be summarized into the brief statement that whereas the stone industry up to about 1900 was chiefly the building-stone industry, with minor values represented mainly by crushed stone, monumental stone, paving, riprap, and rubble, all featuring the stone itself, these products have been in part surpassed in importance by uses in which the stone is an accessory used in the manufacture of different valuable products. In view of the rapid development of manufacturing industries, particularly during the war, there is no occasion to expect a marked change in the present trend of the stone industry. Building stone is expected to increase in use after the abnormally dull war period, but to regain its former position among building materials it must be more thoroughly demonstrated to be not only a superior material but one that can be produced and delivered at a cost low enough to give its superior qualities a broader application, and thus once more to revise prevailing methods of building. Quality at high cost will continue the tendency to restrict building stone to the relatively few elaborate and monumental buildings, whose total annual demand for stone is sufficient to maintain a few well-equipped quarries in profitable existence, without much regard to their geographic location. It is true that the general shortage and expected revival in high-class building may give an impetus to the production of building stone comparable with that of 1897–1902, but the producers who will con-

tinue after that impetus has spent itself are those who can successfully compete with manufacturers of other building materials.

The more important uses of stone in manufacturing industries have already been mentioned, and minor uses are noted on later pages in sections relating to particular kinds of stone. Few of these minor uses are sufficient alone to keep quarries steadily active, but they may become valuable outlets for by-products of quarries whose main output supplies manufacturing, monumental, or building markets. Producers have already been giving attention to the increasing usefulness of stone in the manufacturing industries, and production for these industries may therefore be expected to show further growth.

PRODUCTION.

GENERAL CONDITIONS IN 1918.

The year 1918, as was to be expected, was a most disastrous one for the stone industry in general. Some of the leading products, notably crushed stone, building stone, and paving stone were regarded as "less essential" to war activities, except for local construction work, and the natural stagnation of construction work was thus intensified by restrictions placed by the War Industries Board upon output, labor supply, and transportation facilities. Several rock products, however, although not hailed as "war minerals," were nevertheless very essential to the successful prosecution of the war. Limestone for flux and various important chemical uses, and dolomite and ganister for refractory use were most noteworthy in this respect, and proposed novel uses of vesicular basalt for lightweight aggregate in concrete ships and of large granite blocks for the walls of acid towers illustrated other special war-time uses of "less essential" materials that bade fair to be realized, had the war continued for a year longer. These war-time uses are considered in the sections devoted to the respective stones.

Crushed stone, although its production was greatly curtailed during the war, must nevertheless be regarded as a war material. One of the first projects carried out by the National Research Council was an investigation of the materials available for rapid road construction in the States along the Atlantic and Gulf coasts. Large quantities of crushed stone were used in construction of roads in the vicinity of cantonments and other military and industrial centers where improvement of roads was of prime importance, but these were far from enough to offset the decrease in use elsewhere, which was intensified by lack of transportation facilities. In contrast to this condition it is stated that in France the demand for crushed stone was so great during the war that to it was given priority in shipment subordinate only to men, food, and munitions. Some of the French quarries supplying crushed stone were equipped with American machinery and operated by American engineers. One of the requests made by the War Department to the United States Geological Survey in 1917 was the preparation of a map showing the available road materials in the territory to be occupied by American troops between Verdun and the Swiss border.

This brief comment on the military uses of stone, though of little satisfaction to the producer whose output was greatly curtailed dur-

ing the war, has a national significance. It shows that our stone resources, adequate to meet all peace demands, have also proved easily equal to the special requirements of war. They are low-priced commodities and subordinate to such leading commodities as coal, iron, and copper; but they remind us forcibly that abundance, proper distribution, and diversity of both subordinate and primary resources are essential to our industrial independence.

PRODUCTION BY KINDS AND USES.

The total value of the stone sold in the United States in 1918 was $82,700,430, a very slight increase (0.59 per cent) over the value in 1917. This increase followed increases of 4 per cent in 1917 and 6 per cent in 1916, and a decrease of 4 per cent in 1915. The increase in 1918, as in 1917, was due mainly to limestone, whose value increased 6.9 per cent, following an increase of 12 per cent in 1917. and in part to basalt and related rocks, whose value increased nearly 3 per cent. Other kinds of stone decreased in value from 1 to 18 per cent.

Value of the different kinds of stone sold in the United States, 1908–1918.

Year.	Granite.	Basalt and related rocks (trap rock).[a]	Sandstone.	Marble.	Limestone.	Miscellaneous.[b]	Total.

[a] The term "trap rock" has been variously interpreted and in some localities has been made to include a number of widely different rocks. It is here replaced by the title "basalt and related rocks."

[b] Includes mica schist used for furnace lining, conglomerate, argillite, and various light volcanic rocks used mainly for crushed stone, which can not be properly classified in any of the main groups.

The total quantity sold in 1918 was about 68,563,360 short tons, a decrease of about 18 per cent from the quantity in 1917, which was, in turn, a decrease of about 9 per cent from that in 1916. No stone showed an increase in total quantity sold in 1918, although the sales for a few uses increased in quantity.

Monumental stone increased about 0.5 per cent in quantity and 22.3 per cent in value, passing the record figures for value in 1917. In 1918 nearly 82 per cent of the quantity and 70 per cent of the value of monumental stone was represented by granite, compared with 83 per cent and 70 per cent, respectively, in 1917. The remainder was represented by marble, as the figures do not include negligible quantities of limestone and sandstone. Small quantities of limestone and sandstone sold for monumental use constitute less than 1 per cent of the total quantity and value.

Stone sold for refractories also increased, owing to the continued rapid growth in the use of dead-burned dolomite, which offset decreases in sales of ganister, sandstone, and mica schist.

Stone for "other uses" was the only other class of stone to increase in quantity in 1918. This included limestone for agricultural purposes and for whiting, both of which increased in quantity and value. Limestone and marble for flux, which increased so markedly in quantity in 1916 and 1917, decreased 6.5 per cent in 1918, keeping pace with the slight retardation of the metallurgical industries; but their value continued to increase, exceeding that of 1917 by $4,833,422, or 25.9 per cent, owing to a rise in average price from $0.73 to $0.98 a long ton. Crushed stone, after a decrease of 16 per cent in quantity and 1.3 per cent in value in 1917, underwent an additional decrease of about 27 per cent in quantity and 4 per cent in value in 1918, and its quantity sold fell below 30,000,000 short tons for the first time since 1906. It still remained the leading stone product, however, exceeding flux by more than 2,580,000 short tons.

Continued depression, caused by war conditions and intensified by restrictions imposed by the War Industries Board, accounts for the decrease in the quantity of stone sold for all other uses. Building stone, after a decrease of 30 per cent in quantity and 17 per cent in value in 1917, underwent an additional decrease of 51 per cent in quantity and 38 per cent in value in 1918, and in all probability fell to the smallest quantity and value sold since 1880, although accurate statistics are not available prior to 1898. Paving blocks decreased nearly 42 per cent in quantity and 37 per cent in value; curbing decreased 59 per cent in quantity and 53 per cent in value; flagging though decreasing 23.5 per cent in quantity made a slight increase (nearly 5 per cent) in value, evidently because work well under way in certain places before restrictions in output were imposed was allowed to proceed.

Stone sold in the United States in 1917 and 1918.

[a] Revised.
[b] Limestone alone in 1917; limestone and marble in 1918.
[c] Ganister, mica schist, and dolomite.

This is the second report in which a full statement of the total quantity as well as the total value of the stone sold is given. The figures of quantity are particularly timely in showing the actual change in volume of the industry, which is not reflected by figures of value, owing to the great and rapid advances in price. On account both of the different units of quantity reported by different producers and of the different measurements used for the various products the accurate conversion of all of them to one unit (the short ton) has presented difficulties and has necessitated estimates based on the specific gravity of the various stones. Estimates were necessary also on less than 5 per cent of the total value of the entire output, for which no quantities were given by the producers, but data for estimates in this report are more complete and accurate than those used in the report for 1917. The figures for 1917 have been revised accordingly.

The figures in this as in previous reports represent stone produced and sold or used by the quarrymen. They include only such manufactured products as are put on the market by the quarrymen themselves—some building and monumental stone, crushed stone, flagstone, curbstone, and paving blocks. The value given to these manufactured products is that received by the producer free on board at point of shipment. The value given for the rough stone sold to local trade is, so far as ascertainable, that of the stone at the quarry, but occasionally, if the producer also delivers the stone, includes the cost of delivery. In a few places, where the producer has a long haul to market or to a railroad shipping point, this cost materially increases the selling price.

As in the report for 1917 the kinds of stone represented in this report are classified as granite, basalt and related rocks (trap rock), marble, limestone, sandstone, and "miscellaneous."

"Granite" includes true granite and also such allied rocks as monzonite, syenite, and gneiss. From time to time small quantities of dark igneous rocks, such as diorite and gabbro, used for monumental and building work are also included with granite.

"Basalt and related rocks," included under the term "trap rock" until 1914, comprise, besides typical basalt and diabase, fine-grained diorite, gabbro, and other basic rocks which are less common in occurrence but are similar in chemical and physical properties and are used largely as crushed stone.

"Marble" includes a small quantity of serpentine quarried and sold as marble in California, Georgia, Maryland, Massachusetts, Pennsylvania, and Vermont, and also (when produced) a small quantity of the so-called onyx marble or travertine obtained from caves and other deposits in Kentucky and other States.

The "limestone" represented in the tables of this report does not include limestone burned into lime, bituminous limestone, nor limestone entering into the manufacture of Portland cement. Separate reports are made on the lime, asphalt, and cement industries.

"Sandstone" includes the quartzites of South Dakota, Minnesota, and Wisconsin, and the fine-grained sandstones of New York and Pennsylvania, known to the trade as "bluestone." As "bluestone" is the product of a distinct local industry its production is shown separately from that of the other sandstones. "Bluestone" is also quarried in New Jersey and West Virginia, but this output is small

and is not separated from sandstone. In Kentucky most of the sandstone quarried and sold is known locally as freestone. The figures given for sandstone do not include the value of the grindstones, whetstones, and pulpstones made from sandstones quarried in Arkansas, Indiana, Michigan, Ohio, and West Virginia. These products are included in the report on abrasives. Sandstone crushed into sand and used in the manufacture of glass and as molding sand is considered in the report on sand and gravel.

"Miscellaneous" includes light-colored volcanic rocks, including tuff, rhyolite, trachyte, andesite, and some mica schist, which have previously been classed with granite or basalt; flint rock, previously classed with limestone; conglomerate, argillite, and mica schist used for furnace lining, previously classed with sandstone. The separation may not be complete for 1918, but it is hoped to make the classification better as more knowledge is obtained of the character of the stone for which statistical reports are made.

PRODUCTION BY STATES.

In 1918, as in 1917, production was reported from 50 States and Territories. Pennsylvania, Ohio, and Vermont in 1918 continued to be the three ranking States in value of stone produced. New York, which was fourth in 1917, was passed by Michigan, which advanced from sixth to fourth place. Indiana, which ranked fifth in 1917, dropped to eighth place. Of the 46 States whose individual production is shown on page 1207, 19 increased and 27 decreased in the value of their output. In the region east of Mississippi River 12 showed increase and 13 decrease; in the region to the west 7 showed increase and 14 decrease. As would be expected from the figures of production by uses, most of the important States (Pennsylvania, Ohio, Michigan, West Virginia, Alabama, and Virginia) with increased value of output are States which supply large quantities of limestone to metallurgical and manufacturing plants; the same is true of less important States with increased value, most of which are west of Mississippi River. Exceptions to this rule are New Jersey, with increased output of furnace flux and limestone for agricultural use; Georgia, with increased production of limestone for agricultural and industrial uses; New Hampshire, with increase in both quantity and value of monumental granite sold; South Carolina, with increase in crushed granite sold; and Rhode Island, with increase in granite for monuments and building. Of the States showing decreased value Indiana, whose principal output is limestone for building, was the most severely affected, its value decreasing 37 per cent. The other prominent States with decreased value produced mainly building and crushed stone.

The number of plants reporting operations continued to decrease, from 2,647 in 1917 to 2,118 in 1918. In only six States of comparatively small production, Washington, Wyoming, New Mexico, Idaho, Mississippi, and the District of Columbia, did the number of producers increase. The abnormal conditions doubtless hastened the reduction in number of producers. Some small quarries were closed on account of the enlistment or draft of the owner or operator. In several States quarries were taken over by the United States Government

early in 1918, and held until after the signing of the armistice. From very few of these has it been possible to get the record of output while under Government control, as the quarries were held so short a time that records of operations had not become systematically kept. The expected strong demand for structural stone with return to normal conditions may tend to encourage small operators to resume business, but unless this demand is accompanied by a considerable decrease in cost of operation it is not likely that the number of operators will be materially increased. The present stage in the evolution of the stone industry involves diminution in the number of operators, only those with adequate capital and equipment continuing in business.

Value of stone sold in the United States, 1917 and 1918, by States.

1917.

Rank of State.	State.	Total value.	Percentage of total.	Number of plants.

EXPORTS.

The following tables of exports were compiled by J. A. Dorsey from the records of the Bureau of Foreign and Domestic Commerce, Department of Commerce.

Stone exported from the United States, 1913–1918.

Kind.	1913	1914	1915	1916	1917	1918
Marble and stone, unmanufactured	$606,745	$559,556	$400,510	$403,303	$572,097	$552,261
All others, manufactured	1,250,147	803,686	635,614	1,077,447	1,108,185	1,208,164
	1,856,892	1,363,242	1,036,124	1,480,750	1,680,282	1,760,425

After a decline during 1914 and 1915, there has been a steady increase in total value of exports during the last three years, and the value for 1918 is only $96,467, or 5 per cent, less than that of 1913, the latest normal year. The advance in 1918 was made by manufactured stone. The unmanufactured stone, including marble, underwent a small decrease.

Stone (including marble) exported from the United States in 1917 and 1918.

To the North American countries as usual is credited the greater part of the shipments of stone as indicated by their value. These countries received 74 per cent of the total in 1918. This is an increase of 6 per cent over 1917 and of about 17 per cent over 1916 and indicates a tendency to return to the more nearly normal figure of 83 per cent, represented by the year 1914. These changes are shown

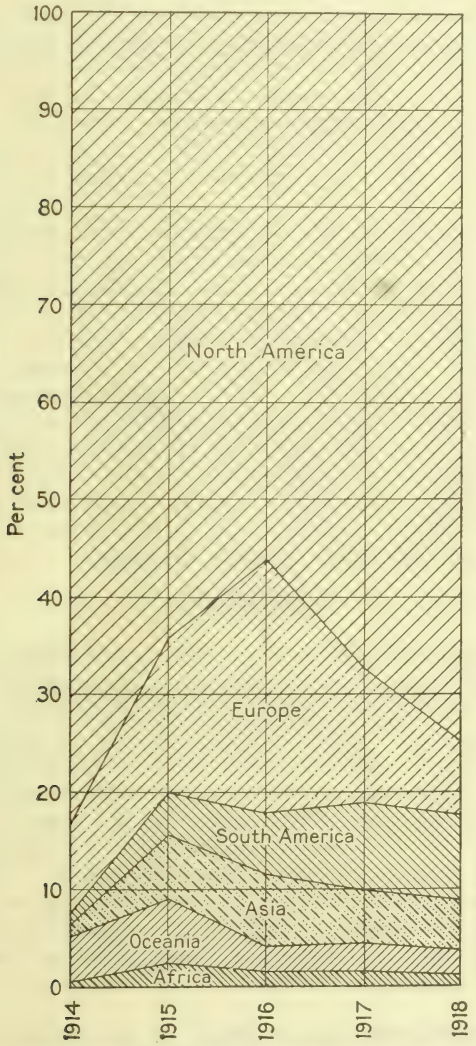

FIGURE 111.—Percentages of stone, by value, exported to different continents, 1914–1918.

graphically in figure 111. The sharp decline in 1915 in value of shipments to North American countries and the increase to European countries and in a lesser degree to all other countries, was followed in 1916 by a further large increase in value of shipments to Europe and all countries except North America. In 1917 the restrictions on shipments to Europe except for essentials caused the figures for that

country to decline sharply with considerable increase for North America and less increase for South America, and decrease for Asiatic countries. In 1918 the decrease to Europe continued, as did the increase to North America and South America. Asia also decreased. The shipments to Oceania and Africa remained in about the same proportion for 1916, 1917, and 1918.

Of the European countries, France, Great Britain, and Italy received shipments of largest value in 1916, 1917, and 1918. In 1918, however, France and Great Britain decreased 60 per cent and 31 per cent, respectively, in value of stone received from this country, and Italy fell off nearly 40 per cent. Although the value of shipments to Asia, Oceania, and Africa decreased somewhat, there was an increase of $16,947 (161 per cent) in the shipments to Japan. There was also increased value of shipments to China and the Philippine Islands.

The value of the shipments of stone to North America and South America, however, showed increase of 31 per cent and 15 per cent, respectively, in manufactured product, the unmanufactured material showing decrease for each continent and for almost every country. The stone shipped to Canada, the largest customer for the United States, constituted more than 59 per cent of the total value of shipments and about 80 per cent of the value represented by North American shipments. Canada's consumption is about equally divided in value between manufactured and unmanufactured material. In 1918 there was an increase of 39 per cent in the value of manufactured stone received and a decrease of nearly 9 per cent in rough stone. The increase in South America was in the value of shipments to Chile, all the other countries showing decrease.

IMPORTS.

The term "general imports" in this publication embraces both imported articles entered for immediate consumption on arrival and articles entered for warehouse, as distinguished from the term "imports for consumption," which embraces imports entered for immediate consumption and withdrawals from warehouse for consumption. The statement of general imports and the statement of imports for consumption for any period will differ to the extent that the value of the entries for warehouse for the period differs from the value of the withdrawals from warehouse for consumption. The term "entry for consumption" is the technical name of the import entry made at the customhouse and does not imply that the goods have been actually consumed, but simply that they have been delivered into the custody of the importer and that the duties have been paid on the dutiable portion.

The stone imported for consumption in the United States in 1918 was valued at $268,577, which was $412,898, or 61 per cent, less than in 1917, which in turn was 29 per cent less than in 1916. The imports of marble, including the usual small imports of "onyx marble," amounted to $235,430, or 88 per cent, of the total stone imported for consumption, a decrease of $345,992, or 60 per cent, compared with 1917, which was 20 per cent less than 1916.

Stone imported for consumption in the United States in 1916, 1917, and 1918.

[a] Figures for January to June, inclusive.
[b] Figures for July to December, inclusive.
[c] Includes Barbados, Trinidad and Tobago, China, British India, Hongkong, and Australia.

Almost the entire value of general imports represents marble imported from Italy, England, and France, nearly 96 per cent coming from Italy alone. That credited to England may include Grecian marble reexported. Imports from Mexico, whose value decreased from $35,657 to $3,257 in 1917, amounted to only $228 in 1918. Onyx marble imported for consumption in 1918 amounted to $3,179. As the greater part of this is believed to have come from Mexico the difference in value indicates that in 1918, as in 1917, a much greater quantity was taken from warehouses than was brought into the country. The value of marble imported from or through Canada in 1918 was nearly ten times that in 1917 and more than three times that in 1916.

Monthly returns from January to April and July to August, 1918, show that only a little more than half of the total value of marble and onyx imported from Europe and Canada was represented by stone received prior to the signing of the armistice, whereas most of that from Asiatic and other ports was received during that period. Receipts from France and England were almost nil between March and September, the period of most intense submarine activity and of partial embargoes on "less essential" commodities. Those from Italy, low in January and February, doubled in both March and April, and then declined to comparative insignificance until November. Most of the imports, including shipments from many if not all the countries of origin, were entered at New York. Philadelphia received some shipments from Italy, France, and Japan; Chicago and St. Louis shipments from Italy; San Antonio, Tex., shipments from Mexico; San Francisco, shipments from Japan and Italy; and Hawaii, a shipment from Australia. A small part of the marble

from England was entered at some port in Ohio, and at least one shipment from Canada was entered in Vermont.

The expected revival of commercial enterprises and the consequent attention being given to tariff regulations have led some of the manufacturers and dealers of the United States to start a movement with the United States Tariff Commission looking to the increasing of the tariff on all finished marble work now brought into this country free of duty. At present there is a duty of 50 cents per cubic foot on the rough quarried marble, 75 cents on sawed or dressed marble, 6 to 12 cents on slabs or tiles, according to their thickness and rubbed or unrubbed surfaces, 45 per cent ad valorem on all other manufactured marble, and 20 per cent ad valorem on loose mosaic cubes.

The value of granite imported for consumption continued to decrease, owing to the almost complete cessation of imports of dressed stone, whereas the quantity and value of rough granite remained about stationary. The almost stationary price of this rough granite (about 52 cents a cubic foot in both 1917 and 1918) is in keeping with the small decline in average price of domestic rough granite, which was due to a large output of low-priced stone in eastern Pennsylvania. No specific data regarding countries of origin are available, but it is presumed that most of the granite imported came originally from the Scandinavian peninsula.

The value of imported stone other than marble, after decreasing nearly 60 per cent in 1917 decreased 66 per cent more in 1918, rough and dressed stone decreasing in about equal proportion. Data regarding countries of origin are incomplete, but are sufficient to show that more than half the total value in 1918 represents stone from France. Stone from England was valued at more than $3,000, stone from Scotland less than $3,000, and stone from Canada less than $2,000. Small shipments came from Mexico and Japan, and insignificant quantities from Hongkong, China, and Brazil. Probably all the French stone and most of the English and Scotch stone was entered at New York. A small quantity of English stone was received at ports in Massachusetts and Rhode Island. Much, if not all, of the Canadian stone was entered at Buffalo, N. Y., and ports in Michigan. Most of the Japanese stone was entered at Hawaii, San Francisco, and ports in Oregon and Washington, an insignificant quantity being received at New York.

Most of the "other" stone imported from Europe was received during or before March, when the embargo was placed on imports of monumental and building stone. Shipments from France and Scotland, however, were received during August and later months, presumably as return cargoes which could be loaded without delay to shipping of essential war material. The embargo continued until May 22, 1919.

GRANITE.

GENERAL STATISTICS.

The granite sold in the United States in 1918 amounted to 3,827,400 short tons, valued at $14,466,423, about 5.6 per cent of the quantity and 17.5 per cent of the value of the entire output of stone for the year, compared with 7 per cent and 19 per cent, respectively, in 1917.

The figures for granite in 1918 showed a decrease of 31 per cent in quantity and 7 per cent in value from those for 1917, which in turn were 40 per cent and 11 per cent less than those of 1916, and were the lowest recorded for value since 1901. The adverse conditions of 1916 and 1917 were intensified by concentration of industrial activity on the winning of the war.

In 1918, as in 1917, granite was sold in 30 States, including the District of Columbia. Of the 25 States, the value of whose output is given in the table below, 11 showed increase and 14 decrease. The States with increased value include Minnesota, Montana, New Hampshire, and Rhode Island, whose principal output is monumental stone, although building stone was also important in New Hampshire and Rhode Island; New York, whose leading products were paving and crushed stone; Pennsylvania, whose rough building stone represented about one-half the value; Virginia and South Carolina, whose outputs were largely crushed stone; Oklahoma, Washington, and the District of Columbia, whose output values are not itemized. As shown in the review by States, those States whose outputs of building, paving, and crushed stone increased were favored by war contracts. The large apparent decrease in the granite figures for Maryland was due somewhat to the transference of a quantity of stone more nearly allied to the basaltic rocks to the section of this report dealing with basalt.

Value of granite sold in the United States, 1914–1918.

Total (quantities approximate, in short tons).	[a] 5,564,200	15,544,957	3,827,400	14,466,423

[a] Estimated in part.

Crushed stone constitutes by far the greatest part of the quantity, 55 per cent in 1917 and 54 per cent in 1918, and is the only product exceeding 1,000,000 short tons. Riprap, which exceeded that figure in 1917, decreased nearly 39 per cent in 1918. Building stone, which amounted to about 6 per cent in 1916 and 5 per cent in 1917, rose again to 6 per cent in 1918, in spite of its continued marked decrease in actual tonnage. Monumental stone, in spite of decrease in actual tonnage, has risen from 3 per cent in 1916 to 5 per cent in 1917 and to 7 per cent in 1918, exceeding both building stone and paving in quantity. Paving stone also, in spite of decline in actual quantity, rose from 5 per cent in 1916 to about 7 per cent in both 1917 and 1918. In value, however, monumental continued to gain and in 1918 constituted nearly half (48 per cent) the total value of granite sold. Building stone, which had been ranking second in value, was passed by crushed stone in 1918. The values of the different granite products sold since 1898 are shown graphically in Plate XIII.

Granite sold in the United States in 1917, by States and uses.

BUILDING STONE.

The total value of granite sold for building stone in 1918 was $2,349,796, a decrease of $811,498, or 26 per cent, compared with that for 1917, which was 20 per cent less than that for 1916. The decrease was mainly in the value of dressed stone in spite of its increase of 31 cents in average price per cubic foot, whereas the price of rough stone, owing to Pennsylvania's increased output of low-priced material, decreased 3 cents a cubic foot. The increase in general average price, following an increase in 1917, is in keeping with the war conditions which have affected all industries.

The stagnation of the building industry, particularly as regards the erection of buildings which call for granite, continued through the greater part of 1919, and although restrictions on production and transportation were removed, the continued unsettled industrial conditions render a material increase in sales of building granite in 1919 improbable. The predicted period of activity in high-class building began in the fall of 1919 and should grow rapidly, although necessarily prevailing high prices have caused some prospective

builders to postpone operations or to alter their plans so as to use cheaper material.

The total quantity of building granite marketed in 1918 was 2,771,013 cubic feet, compared with 3,604,330 cubic feet in 1917 and 7,067,060 cubic feet in 1916. The decrease in 1918 was 23 per cent following one in 1917 of 49 per cent. Pennsylvania alone produced nearly 42 per cent of the total quantity, but it was mainly gneiss suitable for foundations and other rough work and averaged only about 12 cents a cubic foot. Pennsylvania's gain of nearly 100,000 cubic feet was due to increased production in the vicinity of Philadelphia, although many of the quarries were reported as idle or only working part of the time. Massachusetts ranked second with a total of 698,173 cubic feet, its rough stone averaging 35 cents and its dressed stone $2.31 a cubic foot. This quantity is less by 163,448 cubic feet than the quantity for 1917, whereas the average price of rough stone increased 10 cents and that of dressed stone 61 cents a cubic foot. The output of Massachusetts was sold mainly as rough building stone, and the greater part of the output was from Rockport, Essex County, and was used in the construction of dry docks. Maine, with 351,075 cubic feet, 56,090 less than in 1917, was the only other State whose total quantity of building stone exceeded 100,000 cubic feet in 1918. The price per cubic foot for rough stone in Maine in 1918, 29 cents, was 9 cents less, and that for dressed stone $3.80, was 85 cents more than in 1917. A little more than one-half the product was sold as rough building stone and the comparatively low average price per ton would indicate sales of stone of lower grade than in 1917. A considerable quantity of dressed granite was shipped as in 1917 to Annapolis, Md., and used in the construction of Bancroft Hall on the Naval Academy grounds. New York and Rhode Island showed considerable gains. In New York there was an increase in the output of stone quarried at the Blackwell's Island Penitentiary. This stone has been used for many years for construction of prison buildings and of the sea wall around the island. In Rhode Island a large quantity of stone was quarried and dressed for use in the Travelers Insurance Co. building, Hartford, Conn.

The most conspicuous declines were in Connecticut, Delaware, Maryland, New Hampshire, and Vermont. In 1917 building stone was reported as sold from 9 quarries in Connecticut and in 1918 from 6 quarries. In New Hampshire 14 companies furnished building stone in 1917, whereas in 1918 there were only 7 quarries from which this product was sold. Vermont, which is primarily a monumental granite State, furnishes building granite mostly for large building contracts, of which there were practically none in 1918. As to one State, in which the stone is also sold locally, the statement was made that owing to the cost of all building material and to lack of labor, stone was furnished for only one piece of local work, whereas ordinarily material was required for 20 to 40 foundations.

MONUMENTAL STONE.

Monumental granite remained about stationary in quantity and increased in value. The total quantity sold in 1918 was 3,358,431 cubic feet, only 0.4 per cent less than that in 1917, which was 6.6 per

cent less than that in 1916. The total value in 1918 was $6,964,879, a gain of 22 per cent, following a gain of 7.8 per cent in 1917. The average price per cubic foot of rough stone increased 19 cents, and that of dressed stone $1.26. Transportation conditions, though still restricted, were less unfavorable than in 1917, and the demand, dependent more upon individual resources than upon industrial conditions, continued in spite of the necessary increase in price.

Monumental stone includes the stone used for mausoleums, and there was reported as sold for this purpose in 1918 252,329 cubic feet, valued at $788,252, of which 156,631 cubic feet, valued at $725,225, was dressed stone. This does not represent all the stone sold for this purpose, as several of the producers selling rough stock were unable to separate their product. North Carolina, California, Vermont, and New Hampshire were the principal States reporting sales for mausoleums, but they were also reported from Arizona, Colorado, Connecticut, Georgia, Maine, Massachusetts, and Rhode Island.

After the signing of the armistice and with the first coming back to their old trades of the men who had left the quarries for service in the Army or Navy or who had worked at other trades during the war, the wage question became very pertinent in all the large stone quarrying and manufacturing districts, particularly in those producing monumental granite. In the Barre granite district negotiations between the Granite Manufacturers' Association and the Barre branch of the Granite Cutters' International Association resulted in an agreement whereby after January 1, 1919, the Barre granite workers received a minimum wage of $5.52.[7] This meant that granite cutters, polishers, and tool sharpeners received an increase of 72 cents per day. The following figures show the wages granted to cutter's apprentices January 1, 1919, August 1, 1919, and September 2, 1919.[8]

Wages of cutter's apprentices, 1919.

	Jan. 1.	Aug. 1.	Sept. 1.
First 6 months	$1.90	$2.09	$3.00
Second 6 months	2.10	2.31	3.25
Third 6 months	2.30	2.53	3.50
Fourth 6 months	2.60	2.86	4.00
Fifth 6 months	2.90	3.19	4.50
Sixth 6 months	3.25	3.58	5.25

It was stated that this material increase in wage scale was granted in order to encourage young men to enter the granite-cutting trade.

At Concord, N. H., a new wage scale providing for a minimum of $5.52 went into effect February 1, 1919. This was practically the same as that adopted at Barre.

At Quincy, Mass., the cutters demanded $6 a day as the minimum wage, which was refused by the employers, who offered $5.52, as at Barre. The men refused this and quit work December 1. This strike lasted well into 1919. The increase asked for represented a wage increase of about $1.20 a day. The Quincy district, on account of its nearness to the Fore River and Squantum shipyards, suffered more than any other district from labor difficulties.

[7] Monumental News, January, 1919. [8] Monumental News, October, 1919.

Vermont, the leading State, produced about 47 per cent of the total quantity of monumental stone; but as more than 94 per cent of this quantity was sold as rough stone, the State is here credited with only 36 per cent of the total value. The total output in 1918 was 1,563,865 cubic feet, valued at $2,539,263, a decrease of 56,599 cubic feet (3.5 per cent) in quantity but an increase of $338,754 (15 per cent) in value. The rough stone sold increased both in quantity and value, but a decrease of over 42 per cent in quantity of dressed stone caused a decrease in value in spite of increase in average price.

The average prices of Vermont monumental granite from 1913 to 1918 are given below as showing the effect of trade conditions in the stone industry:

Average price of Vermont monumental granite, 1913–1918, per cubic foot.

Year.	Rough.	Dressed.	Average.
1913	$0.98	$3.37	$1.09
1914	1.01	2.99	1.11
1915	1.00	3.69	1.17
1916	1.04	3.66	1.18
1917	1.15	3.57	1.36
1918	1.38	6.05	1.62

Barre is the chief center of the monumental industry in Vermont, and on account of the large quantity of rough stone bought in the vicinity by companies from the quarrymen as rough stock, the following tabular statement furnished by Athol R. Bell, secretary of the Barre Quarriers & Manufacturers' Association, will give an idea of the size of the entire granite industry in 1917 and 1918 in that district, which includes Barre, Williamstown, East Barre, Montpelier, West Berlin, Northfield, and Waterbury.

Estimated output of monumental granite in the Barre district in Vermont in 1917–18.[a]

	1917	1918
Total quarry output (rough stock) cubic feet	1,560,000	1,654,800
Shipped out of Barre district in rough do	260,000	248,222
Manufactured in Barre district do	1,300,000	1,406,578
Light stock consumption in district do	800,000	879,111
Dark stock consumption in district do	500,000	527,467
Number of cutters in district	2,550	1,500
Average daily wage	$5.00	$5.00
Average number of days worked annually	280	260
Total pay roll for year	$3,570,000	$1,100,000
Estimated overhead—50 per cent cutters' wages	$1,785,000	$2,050,000
Estimated light stock valuation, 800,000 cubic feet, at $1.25	$1,000,000	.....
Estimated dark stock valuation, 500,000 cubic feet, at $1.45	$725,000	.....
Estimated polishing cost of 500,000 feet, 1 cubic foot averaging 2 cubic feet, at $1	$1,000,000	.....
Output from saws—one saw equaling 10 men—13 saws in district take place of 130 men at average cost of $6.50 per man and working 280 days a year	$236,000	.....
	$8,316,000	.....

[a] These estimates do not include production by other machinery, such as lathes and sand-blast machines, nor do they include valuation of rough stock shipped outside of the Barre district.

Mr. Bell states that 56 quarries were operated during 1918. These were evidently operated by the 22 companies that reported to the Geological Survey. Twenty-seven active quarry companies reported

in 1917. One hundred and forty-six manufacturing firms were active in 1918. The apparent discrepancy between two statements on page 1222 of the quantity of manufactured stone produced in the Barre district in 1918 results from the fact that some companies which quarry and manufacture stock report to the Survey only the quantity and value of the rough stone from the quarry and others report only that of finished stock. The figures in the foregoing table represent the entire quantity manufactured, most of it by companies which buy their rough stock and are not included in the Survey's list of producers. The difference beween the figures for rough stock in the foregoing table and the total quantity reported to the Survey represents principally the stone wasted in manufacturing.

Regarding industrial conditions in 1918, Mr. Bell says:

> The Barre granite industry in 1918 was naturally subject to a good many of the proscriptions which necessity imposed upon nonessential industries. Our members, while realizing that the loss to them would be measurably irreparable, patriotically cooperated with the Government in sending men, many of them skilled pneumatic tool operators, to the shipyards. In addition there was the prevailing shortage of unskilled labor at the quarries, and of course many men were with the colors.
>
> The arduous winter of 1917–18 cut down the number of working days to 260, the average being 280. Yet the steady introduction of labor-saving machinery partially closed up the gap caused by the decimation of man power in the industry, prolonged suspensions due to extreme weather and fuel orders, and the inevitable shortage of cars.

Massachusetts, which ranked second in quantity of monumental stone made an increase of 33,737 cubic feet, but its total quantity was only about one quarter as much as Vermont's. The total State value was exceptional in decreasing $44,185, and reducing its rank in value from fourth to sixth, owing to the greater output of rough stone, and greatly reduced output of dressed stone.

The total output was 400,475 cubic feet valued at $436,383; an average price of $1.09 a cubic foot. The chief producing district is at Quincy, Norfolk County, although a considerable quantity is produced at Rockport, Essex County, and Milford, Worcester County, with smaller producing localities elsewhere.

Minnesota continued to rank third in quantity and second in value, increasing in both respects. From 1912 to 1916 Minnesota showed steady increase in monumental stone produced, but in 1917 there was a decrease of 20 per cent in quantity, though an increase of nearly 21 per cent in value. In 1918 the output was 283,469 cubic feet, valued at $1,016,643. Although the quantity sold did not equal that of 1916, the total value exceeded $1,000,000 for the first time. The average price was $3.59 per cubic foot, 55 cents more than in 1917. The quarries near East St. Cloud, Sherburne County, and St. Cloud, Stearns County, produced 268,651 cubic feet, valued at $964,290. This represents 95 cent of both the quantity and the value of the monumental stone quarried in the State. Sales of granite for monumental purposes were reported also from quarries at Sauk Rapids, Ortonville, Little Falls, North Redwood, and Morton.

Other States with increase in quantity in 1918 were New Hampshire, Rhode Island, and California. New Hampshire's monumental stone came from Concord, Merrimack County; Milford, Hillsboro

County; Fitz William, Cheshire County; and Redstone, Carroll County. Rhode Island's output was from Westerly. California's output was principally from Raymond, Madera County, but was also sold from quarries near Academy, Fresno County; Penryn and Rocklin, Placer County; Porterville, Tulare County; and included small outputs from Riverside and San Bernardino counties. The value of monumental stone increased in all the more important States, except Massachusetts. New Hampshire's value more than doubled.

PAVING BLOCKS.

PRODUCTION.

Granite paving blocks, valued at $1,547,612 and numbering 25,923,526, were sold in 1918. The quantity of paving blocks produced represented a decrease of 36 per cent, compared with 1917,

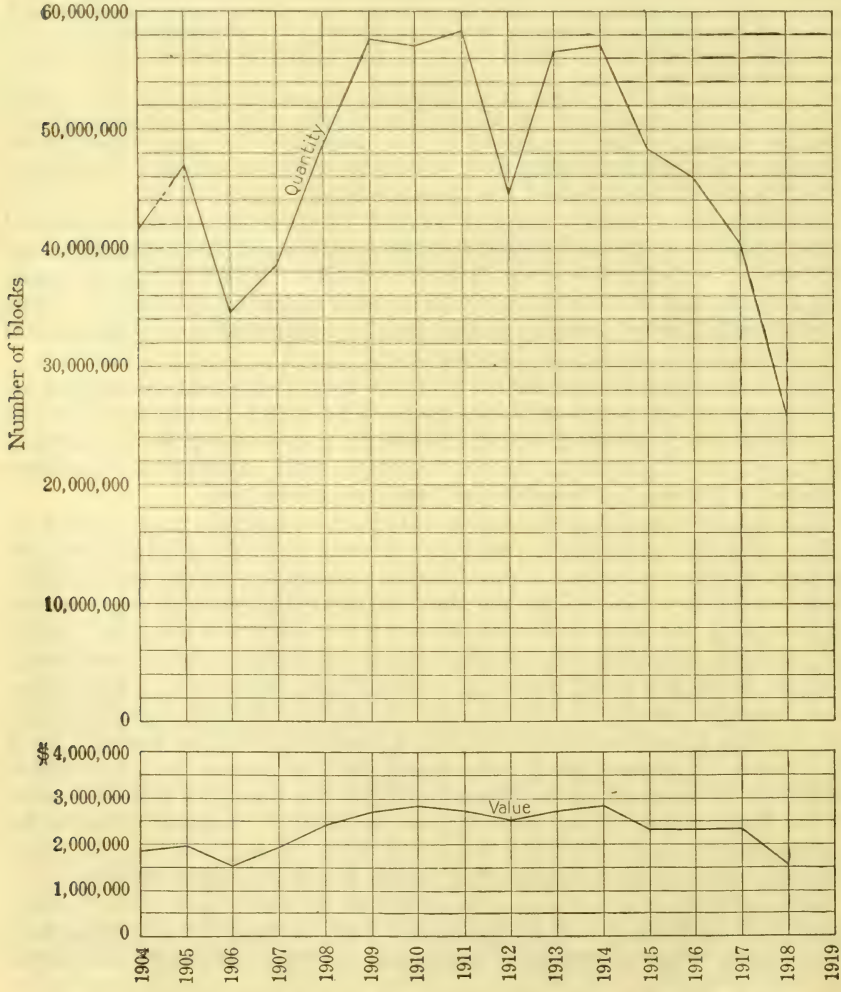

FIGURE 112.—Quantity and value of granite paving blocks sold, 1904–1918.

which in turn showed a decrease of more than 12 per cent, compared with 1916. The value in 1918 was 33 per cent less than that in 1917, which was practically the same as in 1916 and 1915. The average price per thousand during these few years was $48.85 in 1915, $50.73 in 1916, $57.67 in 1917, and $59.70 in 1918, the last being the highest price ever recorded. These figures do not include sales of "durax" blocks. The trend of the paving-block industry is illustrated in figure 112.

Sales were reported from 17 States in 1918, as in both 1916 and 1917. New York and California, whose outputs in 1917 were not disclosed, were the only States to show increase in quantity and value. New Hampshire and Virginia showed small increase in value. Wisconsin, which had been the leading State in 1916 and 1917, ranked fourth in 1918, sustaining a decrease of more than 5,000,000 blocks. Maine regained first place, in spite of a decrease of more than 2,000,000 blocks, and Massachusetts advanced to second place, in spite of a decrease of more than 1,750,000 blocks. New Hampshire, which ranked third in 1918, showed the smallest decrease of any of the leading States—less than 900,000 blocks. North Carolina, Georgia, and Minnesota each showed a decrease of more than 1,000,000 blocks, and the last two became comparatively small producers in 1918. These large decreases reflect the great curtailment of street maintenance and improvement in the larger cities during the war, and presumably forecast a rapid recovery as soon as stable industrial conditions are again established, although in some cities, particularly Boston, the reusing of old blocks in 1919 has continued the restricted production of many producers in New England.

The average price per thousand, as shown below, was lowest in the Southeastern States and California. It was highest in the Central States, and ranged from low to moderate in the New England States and New York.

Average price per thousand of granite paving blocks in 1917 and 1918.

State.	1917	1918
New England States:		
Connecticut	$54.33	$53.45
Maine	61.83	65.73
Massachusetts	58.29	62.93
New Hampshire	43.73	53.68
Rhode Island	63.99	66.25
Vermont	32.54	43.72
Middle Atlantic States:		
Maryland	65.98	68.86
New York	68.78	52.96
Pennsylvania	57.70	83.33
Southeastern States:		
Georgia	45.07	48.17
North Carolina	50.76	52.62
South Carolina	40.00	42.09
Virginia	41.99	48.39
Central States:		
Minnesota	70.52	76.66
Missouri	57.66	60.64
Wisconsin	63.89	60.49
Western States:		
California	38.46	50.72
United States	57.67	59.70

Increase in price of the cheapest blocks was greater than that of the moderate and high-priced blocks. Thus, New Hampshire's price increased nearly $10, Virginia's more than $6, and California's more

than $12 a thousand; whereas, the increase in the moderate prices ranged from less than $1 to more than $4. New York's decrease of nearly $16 was due to a quantity of blocks manufactured from material excavated in New York City. Wisconsin was also exceptional with a decrease of more than $3.

DISTRIBUTION.

The distribution of granite paving blocks from quarry districts to markets is shown in Plate XIV. The New England States produced nearly 64 per cent of the granite paving blocks manufactured in 1918. All of these producing localities are easily accessible to New York and Boston by water or short railroad transportation, and the greater part of the output is therefore shipped to these two cities either for use in the city and its suburbs or for reshipment and distribution to interior markets.

New York.—In 1918 New York and vicinity (including Newark and Hoboken, N. J., Yonkers, Brooklyn, and Long Island City, N. Y.) received nearly 9,400,000 blocks, of which 7,550,000 came directly to New York City. More than 5,630,000 blocks were shipped from West Sullivan, Long Cove, Somes Sound, Vinal Haven, and St. George, Me., to the New York district, 330,000 blocks going to Newark, N. J. The Massachusetts quarries furnished 1,830,000 blocks to this district from Becket and Rockport. Nearly 500,000 blocks from New Hampshire quarries, at Milford and Concord, were shipped to New York. Waterford, Conn., Westerly, R. I., and the New York quarries supplied the remainder.

Boston.—Nearly 5,600,000 blocks were shipped to the Boston district. This includes, besides Boston, small shipments to Quincy, Taunton, Salem, Lawrence, and other neighboring cities and towns. More than 460,000 blocks were shipped to Boston from the Maine quarries, nearly 1,342,000 from the Massachusetts quarries, more than 2,460,000 from the New Hampshire quarries, and the entire output of the Vermont quarries.

Philadelphia.—Of nearly 1,118,000 blocks shipped to the Philadelphia district, including Camden, N. J., and vicinity, and Chester, Pa., nearly 475,000 blocks came from Maine, 270,000 from Massachusetts, 189,000 from New Hampshire, and the remainder from Connecticut and as local shipments from Holmesburg and St. Peters, Pa.

The remainder of the paving blocks produced in New England in 1918 was distributed in supplying local demands or as small shipments to neighboring States. Connecticut paving blocks found further consumption at Ansonia, Conn., and Providence, R. I., and vicinity. Maine blocks were shipped only to the three large districts, and Portland, Me., was supplied with paving blocks from New Hampshire. In Massachusetts Fitchburg, Springfield, and Westford were supplied with local blocks and New Bedford and Fall River, although producing localities, reported home consumption of practically their entire product. New Hampshire blocks were reported as shipped to several towns and cities in Massachusetts, New York, and Rhode Island, as well as used in supplying local demands and those of the large centers. Rhode Island blocks from Westerly were

1920

shipped to Providence and to the New York district. Vermont's output found its entire market in Boston. The principal market for New York paving blocks was the New York City district, but some were shipped from Alexandria Bay to Cleveland and local markets. Paving blocks made in Pennsylvania at Holmesburg and St. Peters supplied the markets of Philadelphia and Harrisburg, Pa., and Camden, N. J. The blocks made in Maryland were all sold in Baltimore near the place of production. Virginia's output from near Richmond supplied the local market and blocks were also shipped to Norfolk and Petersburg. North Carolina shipped to the Virginia markets and to western Pennsylvania, Cleveland, Ohio, Louisville, Ky., and Indianapolis and Kokomo, Ind. Paving blocks made in South Carolina found markets at considerable distance in Cleveland, Ohio, and Fort Wayne, Ind., and those of Georgia, besides supplying Atlanta, were shipped to Cincinnati, Ohio, Louisville, Ky., Indianapolis, Ind., and Chicago, Ill. In previous years, before the restrictions on transportation, blocks from North Carolina, South Carolina, and Georgia supplied markets in other cities of the Middle Atlantic and Eastern Central States.

The paving blocks produced at Graniteville, Farmington, and Doe Run, Mo., supplied the St. Louis market, and shipments were also made to Peoria, Ill. The blocks produced in Minnesota, at St. Cloud, except a small local consumption, were all sent to St. Paul and Minneapolis. Wisconsin, usually a large producer of paving blocks, decreased 60 per cent in output in 1918. This followed a decrease of 20 per cent in 1917.

One of the largest Wisconsin producers of paving blocks directed most of its energies to the production of ganister.[9] It is thought that about 250,000 Wisconsin blocks were shipped to Milwaukee, Wis.; 367,000 to Detroit, Mich.; 1,602,000 to Cleveland, Ohio; and 2,413,653 to Chicago, Ill. These cities are well located for the reshipment of blocks, so it is not possible to give their exact consumption. The granite paving-block industry in California was confined to three localities in southern California, which shipped to southern California to San Diego and Los Angeles, and one at Rocklin in Placer County, which shipped probably to the cities on San Francisco Bay.

The paving-block supply of the large cities is sometimes supplemented by blocks of stone taken from old structures that are being torn down. According to Stone,[10] the Board of Public Works of San Francisco was planning to let a contract to cut paving blocks from the stone once forming the foundation of San Francisco's old city hall at a cost of $37.50 a thousand. This would entail a considerable saving, the market price being $60 a thousand and the blocks hard to obtain. These blocks were to be used for "leaders," the blocks which lie next to the rail and receive the hardest usage, along the lines of the municipal railway. Old foundations have also been recut for paving blocks in the New York City district.

Durax paving blocks sold in 1918 amounted to 1,337 short tons, valued at $9,106, of which the greater part was produced in North Carolina and the remainder in Maine.

---

[9] Stone, August, 1918, p. 317.

[10] Stone, August, 1917, p. 419.

RUBBLE AND RIPRAP.

Rubble and especially riprap both decreased in quantity and value in 1918. Massachusetts, the leading producer of rubble, produced slightly more than 62,000 short tons, after an insignificant production of 8,000 tons in 1917. Georgia, which led with nearly 37,000 tons in 1917, produced less than 14,000 tons in 1918. These figures once more illustrate the local and temporary conditions affecting the quarrying of rubble.

California was the only State with a considerable production of riprap in 1918, its quantity decreasing more than 8,000 short tons. The large decrease for the country was presumably due to curtailment of river and harbor improvement work.

CURBING AND FLAGGING.

Curbing and flagging decreased 59 per cent in quantity and 54 per cent in value in 1918, following decreases of 30 per cent and 16 per cent, respectively, in 1917. This continued decrease was due to the same general causes that affected paving. Georgia, which has been the leading State, underwent the greatest decrease, 53 per cent in quantity and 41 per cent in value, being passed by Maine in quantity and nearly equaled by North Carolina. Massachusetts, which ranked second in quantity in 1917, decreased 49 per cent and ranked fourth in 1918. North Carolina, although decreasing 40 per cent, ranked third in 1918, and New Hampshire, which ranked fifth in 1917, decreased 69 per cent and became an insignificant producer in 1918. Only one State, North Carolina, reported an output of flagging in 1918.

CRUSHED STONE.

Crushed granite represented 54 per cent of the total quantity and 18 per cent of the total value of granite sold in 1918. The production decreased 32 per cent in quantity and 4 per cent in value, following respective decreases of 35 per cent and 24 per cent in 1917. Crushed granite for concrete continued to be the leading product and the only one to exceed 1,000,000 tons, its quantity in 1918 decreasing 28 per cent but its value increasing 1.6 per cent, owing to an increase of 41 cents in the average price per ton. Road metal decreased 42 per cent in quantity and 20 per cent in value, its average price per ton increasing 33 cents. Railroad ballast decreased 22 per cent in quantity and increased 23 per cent in value, its average price per ton increasing 33 cents. The general average price of crushed granite in 1918 was $1.25 a ton, compared with 88 cents in 1917 and 75 cents in 1916. The decline in the use of crushed granite during the war and its proportion of the total quantity of crushed stone is shown in figure 117, page 1310.

OTHER USES.

Granite for "other uses" decreased 25 per cent in quantity and 64 per cent in value in 1918. A considerable quantity of stone quarried near Granite, Okla., by the inmates of the State reformatory and therefore held at less than market value represents more than half of the quantity. This stone was used in the construction of the State capitol at Oklahoma, and on account of the extremely low price was classed under "other" instead of under rubble. Other products

included are stone finely crushed for poultry grit and for artificial stone; stone powdered for use in soap; broken stone used in filtration plants; and stone for the manufacture of rolls used in the manufacture of paper and in chocolate machinery. Since 1916 granite has been reported as used for the manufacture of rolls and scotia beds for grinding chocolate. According to the Monumental News,[11]

this is an entirely new feature of the American granite business. Heretofore the chocolate producers have been using for this purpose a stone produced in Germany. Both the rolls and the beds must be corrugated and ground into each other so as to mesh accurately. An entirely new machine is being built for this purpose (by Jones Bros. Co., at Barre, Vt.). The rolls must all be drilled for the shaft, and a battery of core drills has been built along original lines. It is probable that there will be considerable business of this kind in the future.

Besides Barre, Vt., the quarries at Waterford, Conn., have furnished stone for this purpose.

WAR USES.

Granite has received some attention as a war material. Besides being used in the construction of dry docks by the Navy, it has also been considered, likewise by the Navy, for the erection of nitric acid towers. Trouble with leakage through the numerous joints where chemical brick was used led to the consideration of natural stone that could be obtained in large blocks. Quartzite would be the first choice; but quartzites that are sufficiently nonporous and can be obtained in blocks of desired size are scarce and less conveniently located with respect to the markets in question than are many granites. It is also doubtful if any but granite quarries are equipped to furnish the large blocks specified. At the request of the Navy Department, therefore, experiments on the resistance of granite to corrosion by nitric acid were conducted by George Steiger and G. F. Loughlin of the United States Geological Survey. Preliminary treatment of several granites with 1:1 nitric acid gave a wide range of results, some granites undergoing more or less superficial disintegration within a day or two, some resisting the acid for more than two months with no apparent deterioration other than slight coloration of the acid, and others disintegrating rapidly for a short time. When the granites that showed considerable disintegration were removed from the acid, thoroughly cleaned, and immersed in fresh acid, most of them underwent no further disintegration. Samples immersed for 13 months, then dried and broken open, were bleached to a depth of one-eighth to one-fourth of an inch, but were quite unaffected at greater depth, and most of those having rubbed or polished surfaces gave little or no evidence of superficial disintegration. One sample was thoroughly disintegrated by repeated exfoliation. Biotite (black mica) was the most decomposable mineral present, its decomposition being accompanied by a swelling that was the main cause of disintegration. The development of rift and grain cracks along the rough broken or tooled surfaces was also an important factor in connection with the biotite, and the extent of the disintegration evidently depended on the depth to which these cracks allowed the acid to reach the biotite. In the sample which completely disintegrated biotite was in such large grains and so abun-

[11] Monumental News, June, 1918, p. 254.

dant that new grains were continuously exposed to attack as disintegration proceeded. Quantitative determination of the constituents dissolved showed that other minerals including muscovite, amphibole, pyroxene, and alkalic feldspars were slightly attacked by nitric acids, but the quantity of new material dissolved decreased with each successive treatment. Results of this investigation, so far as it has gone, show that a few granites are practically as suitable as quartzite for the walls of nitric acid towers, and that those granites that underwent considerable superficial disintegration at first lost little if any more material in solution than those that showed little or no disintegration. In other words, as soon as the acid had penetrated to the slight depth of the minute cracks developed on the tooled or roughly fractured surface, disintegration ceased and solution proceeded so slowly as to be negligible. At the rate of solution after a month's immersion, the surface would be worn away at the rate of one-sixth of an inch a year; but the appearance of cubes having smooth surfaces after immersion for a year showed no visible loss of surface other than the removal of a few grains of biotite, and the extent of the corrosion subsequent to the decomposition of the superficial biotite is practically negligible.

NOTE ON THE FOREIGN GRANITE INDUSTRY.

According to the Quarry,[12] the granite industry at Aberdeen, Scotland, was in a worse condition in 1918 than it had been for many years. The effects of the war, following closely a rather dull period, greatly reduced the demand for building stone and paving blocks, depleted the labor supply, and increased the cost of operation. Cessation of imports of rough Scandinavian granite and great depletion of stocks of it, left manufacturers more dependent upon the comparatively expensive native stone. Exports to the United States, formerly an important customer, had declined to insignificance.

BASALT AND RELATED ROCKS (TRAP ROCK).

GENERAL STATISTICS.

The group of road-building rocks which includes basalt, diabase, and some other dark igneous rocks that are very similar in mineral composition and physical properties furnished 9 per cent of the value of all the stone produced in the United States in 1918.

All these products decreased greatly in quantity and all but crushed and "other" stone in value. The increased value of these products was sufficient to increase the total value 2.8 per cent, whereas the total quantity decreased nearly 25 per cent. The increase in value followed decreases of 1.2 per cent in 1917 and nearly 10 per cent in 1916, and brought the total value above that of either of these years, though not up to that of 1915, 1914, or 1913.

Crushed stone represented nearly 96 per cent of the total quantity and 94 per cent of the total value of this group of rocks, and 22 per cent of the quantity and 26 per cent of the value of total crushed stone sold in 1918. Crushed basalt and related rocks decreased 19 per cent in quantity in 1918, after a decrease of 10 per cent in 1917. Its value, however, increased 11 per cent in 1918 after an increase of 1 per cent in 1917. The average price was $1.11 in 1918, compared with 82 cents in 1917 and 73 cents in 1916. Road metal decreased 34 per cent in quantity and 8 per cent in value, after corresponding decreases of 12 per cent and 2 per cent in 1917. Crushed stone for concrete, however, decreased 8 per cent in quantity, after a decrease of 9 per cent in 1917, and again increased in value (25 per cent), after an increase of 3 per cent in 1917. Railroad ballast increased in both quantity (0.4 per cent) and value (34 per cent) in 1918, after decreasing 7 per cent in quantity and increasing 8 per cent in value in 1917. The gains in value of railroad ballast and concrete aggregate were made principally in New Jersey and Pennsylvania and to a less extent in Connecticut and Massachusetts, whose quarries were well situated for supplying the congested railroad and manufacturing region. California, Massachusetts, and New York were the only States whose value of road metal increased.

New Jersey and Pennsylvania, the two leading States, and Massachusetts, which ranked fifth, showed increase in total value, as did the States whose individual values are not disclosed. California, in spite of decrease in all products, furnished by far the greatest quantity of concrete aggregate and next to the greatest quantity of road metal. Its riprap and rubble, however, declined to insignificance. Washington, Oregon, and Hawaii, which have been the other important producers of riprap, also showed great declines, and Washington was the only State with a noteworthy production in 1918.

Paving blocks and building stone also declined greatly in quantity and value. Paving blocks decreased 72 per cent in quantity in 1918, following decreases of 3 per cent in 1917 and 51 per cent in 1916. Paving blocks were produced in the same States as usual, but the number of producers has so generally decreased that only the country's total can be given without disclosing individual production. The average price per thousand was $45.21 in 1918 compared with $36.37 in 1917 and $38.39 in 1916. Connecticut furnished by far the most building stone, but its value was nearly equaled by Pennsylvania, whose stone averaged 21 cents a foot, whereas the average for the country was only 7 cents. Building stone was almost entirely rough stone for foundation work, but Pennsylvania's included a quantity of dressed stone that averaged more than 70 cents a cubic foot.

"Other" stone in 1918 included vesicular basalt quarried in Washington for use in paper-making machinery, which was formerly supplied by German stone.

Maryland appears for the first time among the States producing basalt and related rocks. Its product is gabbro-diorite, quarried at several places in its eastern part. This stone has heretofore been reported as crushed granite. In fact some of the producers may work quarries of both kinds of rocks, or may abandon a quarry of one kind in one year and open a quarry of the other kind the next. The ratio of gabbro-diorite to granite produced in Maryland may therefore be expected to fluctuate.

Value of basalt and related rocks (trap rock) sold in the United States, 1914–1918.

WAR USES.

Soon after the war broke out the United States Geological Survey received inquiries for a domestic supply of vesicular basalt to take the place of stone hitherto imported in small quantity from Germany for use as bedplates and beater rolls in paper-making machinery. The vesicles of imported stone are of irregular shape and sharp edged and are particularly efficient in pulling apart or shredding the wood pulp. As such vesicular stone was not like the stone ordinarily quarried for crushing there was some difficulty in getting satisfactory samples by correspondence with producers. Eastern deposits of course were too amygdaloidal to be satisfactory. Vesicular rock is abundant in the West, and finally stone much like the German stone was located in Washington. This stone is now quarried at two localities in Washington to supply the demand of the paper industry.

Another proposed use of vesicular basalt during the war was crushed stone to serve as lightweight aggregate for concrete ships. The variety that has given best results in the laboratory is highly vesicular, resembling a rubber bath sponge, and is found in certain basalt cinder cones of the Southwest. Only a small porportion of the cinder-cones contain stone of this character in commercial quantity, but deposits close to main railroad lines and large enough to supply the estimated needs of all the Government shipyards for at least a few years were located in New Mexico and southern California. Another deposit worthy of consideration is the cinder cone of Mount Tabor, just east of Portland, Oreg. While search for these deposits was going on, experiments with vesicular burned clay for the same purpose were so successful that the first ships built at the Government yards on the Atlantic coast have used it, but although it appeared to yield an aggregate lighter in weight than basalt in experimental work, that advantage disappeared when production was made on a commercial scale, and at present it is still possible that basalt may prove equally or more satisfactory where transportation costs are not prohibitive. The curtailment of concrete shipbuilding by the Government after the signing of the armistice leaves it to private enterprise to develop this industry and to determine the relative merits of burned clay and basalt for lightweight aggregate.

MARBLE.

PRODUCTION.

The value of marble sold for building and monumental work since 1896 is shown in figure 113. The outstanding features in this figure are: Until 1914 the general though gradual increase in total value of marble for building, compared with the lack of increase in that for monumental work; since 1914 the marked decrease in value of marble for building contrasted with the increase in value of marble for monumental work, which attained a record in 1918 and exceeded that of building stone for the first time. Another striking feature, expressed in the lower part of the figure is the change in 1913, when the total value of marble for interior building first exceeded that for exterior building.

The marble sold in 1918 amounted to about 3,575,670 cubic feet (approximately 305,720 tons), valued at $5,496,389, a decrease of

1.4 per cent (52,080 cubic feet, or 4,410 tons) in quantity and of 13.2 per cent ($833,998) in value. In view of the conditions produced

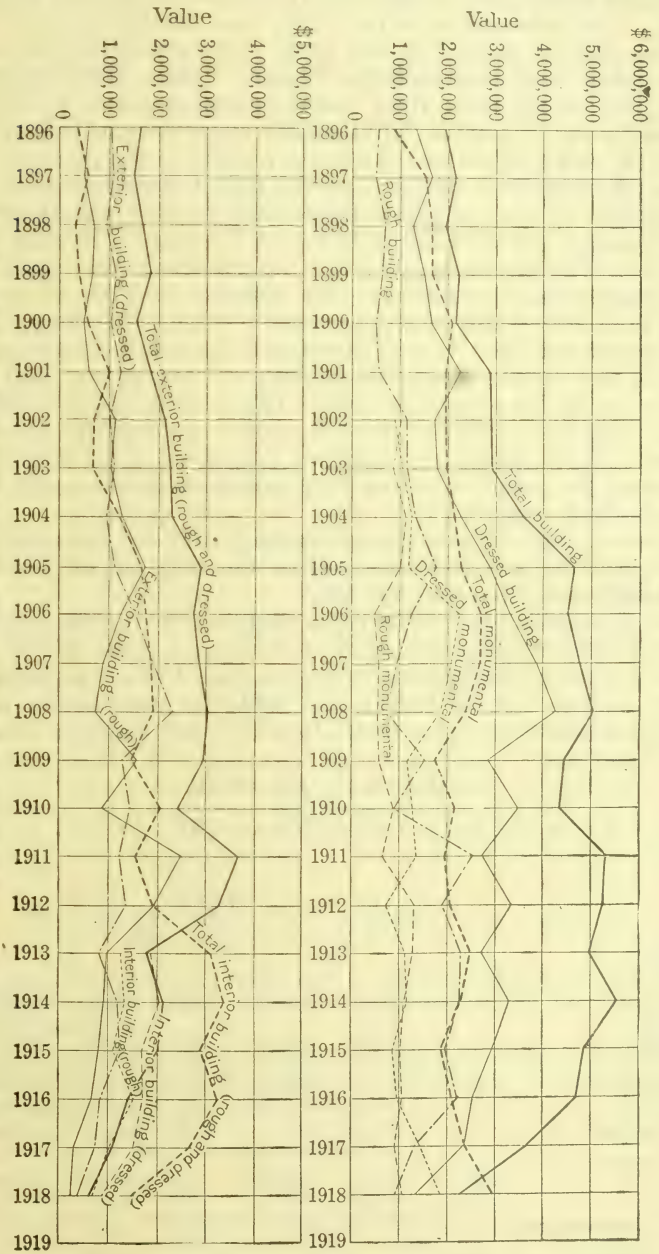

FIGURE 113.—Value of marble sold for building and monumental work, 1896–1918.

in all industries in 1918 by the war the small percentage of decrease in quantity, taken in connection with the larger percentage of decrease in value, would appear anomalous. In 1918, however, less

than 45 per cent of the total output, 1,594,009 cubic feet, represented high-class building and monumental stone, which decreased 26 per cent (562,342 cubic feet) in quantity and about 15 per cent ($900,730) in value. The average price per cubic foot of this kind of marble in 1917 was $2.83; in 1918 it was $3.26. The remaining 55 per cent of the marble marketed included "waste" stone for furnace flux, paper mills, riprap, and road metal; crushed stone for terrazzo, stucco, and poultry grit; and pulverized stone ("marble flour") for agricultural uses and for use as a filler, mainly in the manufacture of putty, paint, soap, and rubber, and for use at chemical works. The total quantity of stone of these kinds sold in 1918 was 169,432 tons (approximately 1,981,660 cubic feet of solid stone), having a value of $296,839. The marble sold for these purposes in 1917 amounted to 125,764 tons, valued at $230,107, an increase in 1918 of nearly 35 per cent in quantity and of 29 per cent in value. The large increase in the quantity of this class of stone and the smaller increase in its value was due to the larger proportion of low-priced riprap and crushed stone in the output in 1918. The average price in 1917 was $1.83; in 1918 it was $1.75. In 1918 many quarrymen, in order to keep their plants active and in good condition, took advantage of any demand for rough stone and its products which could be supplied from their quarries.

The figures given include a small quantity of "onyx marble" quarried by one firm in California, and a quantity of serpentine, for which details are given on page 1245.

In the conversion of tons to cubic feet, or vice versa, in order to obtain a statement of total output an average weight of 171 pounds for a cubic foot of marble has been assumed, but on account of the diversity in the sizes of blocks sold and the irregularity of their shapes no attempt has been made to allow for waste in sawing or cutting the stone.

[a] Approximately.

The total marble sold in 1918 for use as building stone was 880,097 cubic feet, valued at $2,252,262, a decrease of 590,696 cubic feet (40 per cent) in quantity and of $1,450,301 (39 per cent) in value. These figures would indicate that the demand in 1918 was supplied either by stone of lower grade or by stone on which less dressing had been done. Marble for exterior building decreased in output 198,913 cubic feet (38 per cent) and its value decreased $417,315 (38 per cent). A little more than half of this exterior marble was sold as rough stone, and this decreased 25 per cent in quantity and 11 per cent in value, while the dressed exterior stone decreased 48 per cent in quantity and 49 per cent in value. Marble for interior building work, representing over 62 per cent of the total building marble, decreased 42 per cent in quantity (391,783 cubic feet) and 39 per cent in value ($1,032,986). Of the marble sold for interior work 68 per cent was sold as rough blocks, and this decreased 36 per cent in quantity and 35 per cent in value in 1918, while the dressed stone sold for interior work decreased 51 per cent in quantity and 43 per cent in value.

Missouri, Georgia, and New York furnished most of the marble for rough exterior work, and Georgia, Vermont, and Missouri more than 80 per cent of dressed exterior marble. More than one-third of the rough marble sold for interior work was from Tennessee, and Missouri and Vermont together produced a little less than Tennessee. Tennessee furnished about one-half the dressed stone for interior work, but the output from Vermont, although about 45 per cent less than that of Tennessee, showed a much larger value.

Though the trade in building marble was affected by labor conditions and by restrictions that hampered all building operations, the trade in monumental marble, which had shown a decrease in quantity and an increase in value in 1917, showed increase in both quantity and value in 1918, and although the quantity did not equal that sold in 1916 the value was 40 per cent higher than in that year.

Ordinarily the output of building marble is more than twice as much as that of the monumental marble, but in 1918 only about one-fourth more was sold. The monumental marble sold in 1918 amounted to 713,912 cubic feet, valued at $2,947,288, an increase of 28,354 cubic feet (4 per cent) in quantity and of $549,571 (23 per cent) in value. The rough monumental stone sold decreased 9 per cent in quantity but increased nearly 20 per cent in value. Dressed monumental stone increased both in quantity (19 per cent) and in value (25 per cent).

Over 75 per cent of the rough monumental marble and about 60 per cent of the dressed stone was furnished by Vermont, and Georgia was the next largest producer.

The distribution according to uses of marble sold for other purposes than building and monumental work in 1917 and 1918 was as follows:

Marble sold in the United States in 1917 and 1918, by uses.

Use.	1917		1918	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.
Pulverized marble ("flour")	23,293	$58,631	28,815	$86,619
Terrazzo	12,551	37,468	8,350	39,957
Furnace flux	18,932	15,072	61,613	84,899
Riprap	25,000	12,781	33,722	38,909
Road metal, concrete, etc.	45,988	106,155	15,957	21,655
Other uses			20,975	24,800
	125,764	230,107	169,432	296,839

As may be noted, all products increased in quantity and value except the stone reported as sold for use as terrazzo and for miscellaneous uses, but even that sold for terrazzo increased in value.

Pulverized marble includes material used as a filler in many products, principally paper, putty, paint, rubber, and soap, and a small quantity sold for agricultural uses. The production of this "flour," as it is called in the trade, has increased considerably during the last few years, for the product now takes the place of chalk and whiting. In 1917 besides these uses and, exclusive of limestone for agricultural use, 34,983 short tons of limestone, valued at $75,326, was sold for the manufacture of whiting, and in 1918 43,011 short tons, valued at $196,944, was sold.

Under "other uses" is included marble sold to pulp mills, that sold for the manufacture of artificial stone and carbonic-acid gas, and that sold for other uses not specified.

PRODUCTION BY STATES.

Twenty States reported an output of marble in 1918, one more (South Carolina) than in 1917. The number of operators in 1918 was 64; in 1917 it was 69; and in 1916 it was 80.

Vermont produced 50 per cent, Georgia about 21 per cent, and Tennessee about 11 per cent of the total value in 1918, these three States together thus producing 82 per cent of the total value. In 1917 Vermont produced 48 per cent of the total value, Georgia 17 per cent, and Tennessee 14 per cent, 79 per cent in all. Vermont and Georgia marbles are used extensively in both monumental and building work, but Tennessee marble is in demand principally for use as interior building stone. In many States there are only a few producers, so that it is not possible to show the production by States without revealing individual output. The figures in the table showing production by States, however, are itemized as far as they can be without disclosing confidential reports from producers, and neighboring States are grouped together in order to show the relative importance of the marble industry in different parts of the country. Although increase is shown in only two States (Georgia and Mis-

souri) that are listed separately, three others (Maryland, Texas, and Washington) also reported increase.

Value of marble sold in the United States, 1914–1918, by States.

Alabama.—Alabama, whose output increased 16 per cent in value in 1917, showed a decrease of nearly 10 per cent in 1918, but retained its rank as fourth among the marble-producing States. The quantity of stone sold for building and monumental use in 1918 decreased about 25 per cent, whereas stone sold for other purposes (terrazzo, flux, pulverized marble, and riprap) showed a larger tonnage than in 1917. The two producing localities were, as in 1917, at Gantts Quarry and near Sylacauga, Talladega County. Business conditions were reported as satisfactory in so far as amount of work offered was concerned, but labor conditions limited the output of the quarries. Prices were reported as advanced about 35 per cent over 1917, in order to balance the increased cost of labor and supplies.

Alaska.—Alaska's output was greatly curtailed in 1918, as in 1917, by prohibitive freight rates, scarcity of ships and of labor. The only quarry in operation was that of the Vermont Marble Co., at Tokeen.

Arizona.—It was reported that the Dragoon Marble Mining Co., whose quarry is near Dragoon, Cochise County, Ariz., worked a part of 1918, opening up quarries, making roads, and taking out samples preparatory to shipping marble to Los Angeles in 1919.

Arkansas.—The only marble quarrying in Arkansas in 1918 was at Batesville, Independence County. This stone is sold chiefly as exterior building stone and the cessation of building operations that were not connected with war enterprises, as well as problems of labor and supplies, lessened the output of marble for this State.

California.—The value of the marketed production of marble in California in 1918 was $50,776, a decrease of 53 per cent. With the exception of a small quantity sold for terrazzo, this stone was all used for interior building work. The stone classified as marble in this State includes serpentine (verde antique) quarried on Catalina Island, Los Angeles County, and "onyx marble" quarried near Tolenas Springs, Solano County, besides the marbles at Columbia and Sonora, Tuolumne County. Labor conditions were a handicap to the quarry operators, but marble from Alaska was hard to get on account of lack of shipping facilities, and eastern marble was off the market on account of high freight rates, so that the local marble had the advantage of whatever building operations there were.

Colorado.—No production or sales were reported from Colorado in 1918. The Colorado-Yule Marble Co., was a large producer until it went into receiver's hands in 1916. This company first reported sales of marble in 1908, and its product has been shipped quite generally throughout the United States. Large quantities have been used in Los Angeles, Calif., and Denver, Colo., for both building (exterior and interior) and monumental work. The statues over the entrance door of the Cuyahoga County Courthouse, Cleveland, Ohio, as well as some of the interior stonework, are of this marble. Probably its most conspicuous monument is the Lincoln Memorial in Potomac Park, Washington, D. C.

The Colorado-Yule Marble Co. has a large well-equipped plant, which, including the quarries, mills, and railroads with their equipment and the immense marble resources available in undeveloped property, is estimated to be worth more than $2,500,000.[13] For several years the company did not pay its Gunnison County taxes, which aggregated $75,000, and when the company was in the hands of a receiver, without funds and unable to raise $35,000, which would have effected a compromise and a settlement, the county commissioners ordered the plant sold for taxes and finally agreed to sell their claim to a Denver junk dealer. This deal, however, was prevented by injunctions from different parties, one of which was accompanied by a substitute offer of $38,000. No decision had been handed down up to the close of 1918. In June, 1918, the company was permitted by the Colorado Public Utilities Commission to close its railroad, which had been damaged by a washout. It is the desire of the receiver to hold the property intact and in good condition in case the revival of building and monumental business may warrant a better disposal of it.

Georgia.—Georgia's marble production in 1918 was marked by an increase of 7 per cent ($78,661) in value. This State ranks second in value in the marble industry, and in 1918 its output represented 17 per cent of the quantity and 11 per cent of the value of all the building and monumental marble produced in the United States. A considerable quantity of stone for flux, agriculture, whiting, stucco, and terrazzo was also sold from the quarries of this State. The producing localities in 1918 were at Tate and Whitestone, Pickens County.

Maryland and Pennsylvania.—Maryland and Pennsylvania together showed an increase in quantity and value of output in 1918. The increase, however, was for the Maryland production only. The demand for exterior and interior building stone was very poor, and

[13] Stone, November, 1918.

prices were reported as advanced about 30 per cent. Demand for pulverized and crushed marble was good and accounted for the total increase. The producing localities were Cockeysville, Baltimore County, and Cardiff, Harford County, Md. (serpentine), and Easton, Northampton County, Pa. (serpentine).

Massachusetts.—The value of marble quarried in Massachusetts, which in 1917 was lower than for any year since 1901, showed a further decrease (21 per cent) in 1918. The producing localities were Lee and North Adams, Berkshire County, and Westfield, Hampden County (serpentine). Besides the marble used for building and monumental work, a considerable quantity—13,200 tons, valued at $27,363—was used in 1918 for terrazzo, marble "flour," and flux.

Missouri.—The marble marketed in Missouri—196,519 cubic feet, valued at $238,111, in 1918—showed an increase of nearly 5 per cent ($10,591) in value over 1917, but a decrease of 7,998 cubic feet (4 per cent) in quantity. The average price was $1.21 in 1918 and $1.11 in 1917. The marbles of this State are from the Phenix, Greene County, and Carthage, Jasper County, districts. The Carthage stone is also sold as limestone, and a detailed statement of production for 1917 and 1918 is given under limestone on page 1268 of this report.

New York.—The value of the marble produced in New York in 1918 was $135,756, a decrease of 46 per cent. This is the smallest recorded value for marble for this State. The average value of the stone sold for building and monumental purposes was $2.25 per cubic foot in 1918, a decrease of 15 cents a cubic foot. The cessation of practically all building operations in 1918 was the cause of the large decrease, as the marble of this State is primarily a building stone, with New York City as its chief market. The quantity of marble sold for other than building and monumental work was 14,797 short tons, practically the same as in 1917, but the value ($39,718) increased about 10 per cent. The average value per short ton was $2.44 in 1917 and $2.68 in 1918. This stone is sold as pulverized marble or "flour" for agricultural purposes, for paint and soap filler, for riprap, flux, and the manufacture of artificial stone.

In 1918 the active quarries were at Bluff Point, Clinton County, for interior building marble; Wingdale, Dutchess County, for exterior building stone; Gouverneur, St. Lawrence County, for monumental and exterior building stone as well as stone for flux and riprap; Glens Falls, Warren County, for stone for exterior building, and Tuckahoe, Westchester County for stone for terrazzo, agricultural use, soap filler, stucco, and for the manufacture of artificial stone.

North Carolina.—Because of shortage of labor and fuel, the marble quarries at Regal, Cherokee County, N. C., were operated only part of the year with a consequent decrease in quantity, although the average price per cubic foot increased. This stone is used almost entirely for monumental work.

Tennessee.—The marble quarries of Tennessee, which furnish marble chiefly for interior building work, have seemingly been more seriously affected by the war conditions than the other large marble districts. The value of the marble produced in Tennessee in 1918, $599,096, was the lowest since 1905 ($582,229). The total value for 1918 decreased $285,588 (32 per cent) and followed a decrease in 1917 of $115,582 (11.5 per cent). The marble sold for building and

monumental stone in 1918 amounted to 262,913 cubic feet, valued at $582,639, a decrease of 162,419 cubic feet (38 per cent) in quantity and $300,765 (34 per cent) in value. The average value per cubic foot increased from $2.08 in 1917 to $2.22 in 1918. The considerable decrease in quantity reduced Tennessee to third in rank of the marble-producing States in both quantity and value of output.

The quarrymen stated that war conditions made it impossible to obtain enough labor for the quarries; hence production was necessarily so reduced that it was difficult to quarry enough blocks to keep the mills running for filling orders on hand. Unforeseen increases in cost of production and manufacture in the quarries and mills were stated to have caused losses on orders already taken and to have made 1918 the worst year ever experienced in the Tennessee marble industry.

The crushed and pulverized stone sold in 1918 showed a considerable increase, but the average value per short ton ($1.18) was slightly less than in 1917. A quantity of waste limestone is sold annually to manufacturers of lime and the value of this stone is not included in the total.

Tennessee marble is well known to the trade by its different shades of pink, gray, and brown. The present domestic output of black marble is from Vermont and Virginia, but a deposit containing black, green, gray, and blue marble was opened in Tennessee in Gin Hollow, 2½ miles northeast of Flintville station on the North Carolina & St. Louis Railroad, Lincoln County, by the Brighton Marble & Development Co. in 1917. The deposit is 2 miles from the railroad and inability to get a spur track connection is given as the reason that no marble was shipped in that year or in 1918. The varieties of stone and their respective thicknesses, according to a report by R. H. Elliott, are as follows:

	Feet.
1. Green marble ("seafoam-green") with nodules of flint or chert	20
2. Black shale	5
3. Gray marble ("Confederate gray")	10
4. Green marble ("autumn-leaf green")	20
5. Black marble ("duro black")	42
6. Steel-gray marble	5
7. "Bird's-eye antique" marble	25
8. Blue marble ("of doubtful quality")	40

In one section bronze-colored marble, and in another pink marble is present instead of the "autumn-leaf green." All the strata in the foregoing section are above water level, and self-draining quarries may be opened in the slopes. The marble is said to work easily. Partial chemical analyses are as follows:

Analyses of marble near Flintville station, Tenn.

	1	3	4	5	7	8
Silica (SiO_2)	28.29	1.27	1.01	1.27	5.17	12.37
Alumina (Al_2O_3)	.17	.08	.05	.33	.83	1.05
Magnesium carbonate ($MgCO_3$)	26.23	.38	.13	.65	.54	.57
Calcium carbonate ($CaCO_3$)	40.85	96.92	98.85	97.07	91.57	83.82
Phosphorus pentoxide (P_2O_5)	.12	.....	.....	.....	.....	.07
	95.66	98.65	100.04	99.32	98.11	97.88

Analyses 3, 4, and 5 indicate that waste stone from these beds may be suitable for several chemical uses which require a high grade of high calcium lime or limestone.

Texas.—The marble quarry at San Saba, Tex., was in operation in 1918 with practically the same output as in 1917.

Utah.—The only commercial marble operations in Utah in 1918 were at the quarry near Thistle Mountain in Utah County. The entire output was sold for interior building work.

Vermont.—Vermont's production represented 50 per cent of the total value of the marble quarried in the United States in 1918, and nearly 40 per cent of the quantity and 52 per cent of the value of the building and monumental marble sold. In both quantity and value of production Vermont continues to outrank all other States by a wide margin.

The total sales of marble in the State decreased 9 per cent in value in 1918. Excluding a quantity of stone sold for terrazzo, furnace flux, and to paper mills, the marble marketed decreased 197,973 cubic feet (24 per cent) in quantity and $321,844 (11 per cent) in value. The average price per cubic foot was $3.63 in 1917 and $4.26 in 1918. The details by uses of the Vermont marble production are shown in the following table:

Marble sold in Vermont in 1917 and 1918.

a Rough exterior included in dressed exterior.

The stone sold for building, rough and dressed, decreased 284,907 cubic feet (65 per cent) in quantity and $876,815 (about 58 per cent) in value.

The stone sold for monumental work, rough and dressed, in 1918, increased 106,284 cubic feet (28 per cent) in quantity and $575,617 (38 per cent) in value, not enough in either quantity or value to offset the decrease in building stone.

The marble marketed in Vermont in 1918 was from Middlebury, Addison County (rough interior building stone and terrazzo); East Dorset, Bennington County (rough interior building stone); Swanton, Franklin County (dressed interior building stone); Brandon, Clarendon Springs, Danby, Pittsford, Proctor, Rutland, and West Rutland, Rutland County (rough and dressed interior, rough and dressed monumental, rough and dressed exterior, flux, terrazzo, and paper mills); and Roxbury, Washington County (serpentine, for rough interior and rough and dressed exterior building).

Virginia.—The black marble quarries at Harrisonburg, Va., were idle in 1918, owing to labor difficulties and railroad restrictions. Some of the stone on hand, however, was sold during 1918.

Other States.—Small quantities of marble were quarried for local consumption at Alamogordo, N. Mex., Williams, Oreg., Oconee, S. C., and Chewelah, Stevens County, Wash. No production was reported from the quarry of the Michigan Verde Antique Marble Co. near Ishpeming, Mich., but some progress was made on the construction of the spur track to the quarry.

SERPENTINE (VERDE ANTIQUE).

The serpentine represented in the table below is that variety which is used as building or ornamental stone and is known commercially as green marble or verde antique.

No serpentine was sold rough for use as exterior building stone either in 1917 or in 1918. The output in 1918 was valued at $135,138, which was $59,778 less than in 1917. Sales in 1917 and 1918 were reported from Vermont, Pennsylvania, Massachusetts, California, and Maryland, the States being here named according to value of output, one producer reporting from each State.

Serpentine (verde antique) sold in the United States in 1917 and 1918.

NOTES ON FOREIGN MARBLES.

Statements of American consuls published in commerce reports and statements given in trade journals on the conditions of the marble industry in different countries have been abstracted and are given below as being of particular interest to the domestic marble industry at the present time.

In the following notes on foreign marbles mention is made of only such marbles as have been called to the attention of the writers either on account of recent development or because their output has a direct effect on the marble industry of the United States.

ITALY.

The publication Stone[14] quotes the Italian journal L'Industria to the effect that there was a decrease of nearly 8 per cent in the value of the stone produced in Italy in 1916.

This decrease was said to be caused principally by the decreased output of white and colored marbles, which in 1915 began to undergo great decrease on account of scarcity of labor, stagnation of commerce, increased cost of raw materials, and great rise in freight rates for foreign countries, which imported nearly all the worked marble. In 1916 the production of rough and worked marble in Italy fell from 246,883 to 200,700 (metric) tons. This decrease was partly due to the quarries of the Apuan Alps, which produced only 171,865 tons in 1916 compared with 199,724 tons in 1915. The output of the Veronese and Vicentino quarries fell from 9,776 and 11,150 tons in 1915 to 3,250 and 5,126 tons, respectively, in 1916. Of the total rough marble quarried 122,732 tons was worked, 98,660 tons in sawmills and 24,072 in workshops. The rough marble remaining represented 49,133 tons. Exports from Italy, which as in the past consisted of superior qualities of marble principally sawed rather than rough, showed a decrease of 13,451 tons in 1916, although there was some increase in exports to France, Switzerland, and the United States. The number of workmen at the Apuan quarries in 1916 was 5,077, compared with 6,960 in 1915, the number of workings remaining about the same—173 instead of 174. The cost per ton of marble quarried decreased from 22.93 to 19.73 lire, while the yield per workman increased from 28.7 tons in 1915 to 33.71 in 1916.

The same journal[15] publishes the following figures which indicate the extent of the decrease in the quantity (metric tons) of marble shipments from Carrara and Massa, important marble centers of Italy, from 1913 to 1917—Carrara, 1913, 245,600 tons; 1914, 207,001 tons; 1915, 110,850 tons; 1916, 101,015 tons; 1917, 69,017 tons; Massa, 1913, 51,250 tons; 1914, 44,118 tons; 1915, 25,120 tons; 1916, 13,722 tons; 1917, 9,131 tons.

According to a report of the United States Consul at Genoa, Italy,[16] an official decree published May 2, 1917, provided that a portion of the proceeds of a tax levied on marble quarried within the limits of Carrara might be used in meeting the expenses of constructing and operating the port of Carrara. It stipulated, however, that the city must contribute not less than one-fourth of the gross proceeds of this tax to the marble workers' relief fund.

Marble quarrying at Carrara was at a standstill, owing to shortage of labor, fuel, and transportation facilities.[17] Marble, furthermore, was on the embargo list of most countries. After the armistice was declared, the workmen asked and received a further increase in wages and had the length of their working day reduced to eight hours. These changes have caused a further increase in selling price of marble, though less in proportion than the increase in costs. Increase in local transportation charges is likely to raise prices still more. Stocks of marble have become greatly depleted and together

[14] Stone, December, 1918.
[15] Stone, September, 1918, p. 419.
[16] Commerce Repts., June 11, 1917.
[17] Stone, May, 1919, p. 211.

with continued shortage of labor and transportation facilities are likely to curtail export trade for some time.

FRANCE.

The exportation and reexportation of marble intended for England, the uninvaded part of Belgium, Italy, and countries outside of Europe without special authorization were permitted by the French minister of finance, October 7, 1918, according to the American consul general.[18]

BELGIUM.

It is stated[19] that the black marble quarries of Belgium, which prior to the war shipped their product to all parts of the world, were used by the Germans as emplacements for their large guns and that the marble immediately beneath the guns was so badly shattered that the quarries will be useless for the production of marble for building and monumental work without the expense of removing a large quantity of waste stone and rehabilitating them.

Belgium[20] had some of the largest and best equipped quarries in the world. That country had specialized in stoneworking machinery and especially in the application of electricity to the quarrying and working of stone. It is reasonably certain that Germany requisitioned the greater part of this equipment.

SPAIN.

Concerning black marble the American consul at Santander, Spain,[21] says that this Province possesses valuable marble quarries of which the King Alfonso quarry, better known as "Flanders granite," produces black marble and the Queen Victoria quarry produces marble of different colors, the veiny kind being specially abundant. The deposits of both kinds of marble are of considerable extent.

SPITZBERGEN.

Considerable interest was revived recently, according to the Building World,[22] in deposits of colored ornamental and building marble on Marble Island, one of the Spitzbergen Islands lying to the north of Norway. The deposits which contain marble of wide range of color and rich contrasts were said to be very accessibly located for transportation on the least icebound bay of Spitzbergen, where it would be possible to ship marble during the greater part of the year. The Northern Exploration Co., 62 London Wall, London, England, had the enterprise in charge, and it was reported that the deposits would be worked immediately, but according to more recent information the deposits are too much fractured and the stone too friable for architectural purposes.[23]

[23] Letters by Rolf Marstrander and R. H. Blumenthal, Mining Mag. (London), vol. 21, No. 1, p. 40, July, 1919.

These statements were opposed by an official of the company, who maintained that large blocks of sound stone were to be found at shallow depth, as shown by borings.[24] It remains to be seen, therefore, whether development work proceeds to the producing stage.

Some exploration work, in which American machinery was used, was done on these deposits six or seven years ago, and a brief account of them was published in 1913.[25]

MEXICO.

The principal producing locality in Mexico is in Lower California, but a deposit near Salina Cruz is reported by the American consul[26] as in the mountainous portion of the Tehuantepec River valley, along the Toquisistlan, a tributary stream, where several valuable fields are known to exist. The developed quarries are 4 miles from Toquisistlan and 33 miles from Tehuantepec, the nearest railway station. These have been worked for a considerable period, and in the four or five years preceding 1910 some 30,000 cubic feet of onyx was quarried and exported to the United States. No onyx is at present being brought out of the fields, as this territory is dominated by brigands. Transportation is the principal obstacle to the successful development of these fields, as up to the present all onyx exported has been hauled to Tehuantepec. The onyx in this field is largely of the white and pink varieties, some of the remainder being beautifully mottled. It is said to be superior to that of Lower California, bringing $7.50 a cubic foot delivered on shipboard at Boston, Mass., whereas the Lower California onyx sells at $5 a cubic foot. The size obtainable is limited only by transportation facilities. With the present facilities it is not possible to bring out slabs larger than 3 by 6 feet, and 6 inches thick.

CUBA.

Exploitation and development work on marble deposits located on the Isle of Pines, Cuba, has been carried on from time to time, and the consul general at Nueva Gerona in a report dated March 24, 1919, states that a deposit of marble of remarkable fineness and beauty of color, located near Nueva Gerona, is being put in condition for commercial use. The marble, which is white, is being taken out in large blocks and will be cut and polished at the quarry in order to reduce the cost of transportation. Some of the machinery for this work has already arrived from the United States and is being erected under American supervision. The marble is expected to find a market in both Havana and in the United States.

GREECE.

The consul general[27] at Athens, Greece, states that the quarrying of marble in Greece in the last few years has practically ceased and that the English company which controlled most of the quarries has

[24] Mansfield, Ernest, Mining Mag. (London), vol. 21, No. 2, p. 96, August, 1919.
[25] Stone, May, 1913, pp. 241–242. Quoted in part from the Stone Trades' Journal, London.
[26] Commerce Repts, Jan. 30, 1919, p. 452.
[27] Monthly report on commerce and industries, February, 1919.

sold the greater part of the machinery and proposes to work the quarries in a more primitive manner on account of the cheapness of labor.

In a later report [28] the production of marble in Greece in 1916, 1917, and 1918 is given as follows:

Marble produced in Greece, 1916–1918.

	Produced (metric tons).	Sold.		
		Metric tons.	Value.	Average price per ton.
1916	341	251	$13,057	$52.02
1917	173	390	22,059	56.50
1918	297	1,740	.....	.....

It is inferred that sales in 1917 and 1918 were made from stock on hand. It is further stated that practically the only firm exporting marble from Greece—the Grecian Marbles (Marmor) (Ltd.)—reports that it was unable to ship any marble in 1919, owing to freight rates and import and export restrictions. The operations of this company are described by the consul as follows:

Owing to transport and shipping difficulties the colored-marble quarries at Larissa and on the islands of Tinos, Skyros, and Syra were not worked during the year (1918). The Pentelic quarries were worked for a few months to supply marble for local orders, the total amount extracted being 297 tons. Practically the whole stock on hand from previous years was sold to Greek merchants and contractors in Attica. Total sales amounted to 1,740 tons in 1918, compared with 1,196 [29] tons sold in 1917. Local business was fairly good during the year and there are good reasons to believe that there will be a large expansion in building operations as soon as conditions improve and construction materials become again accessible.

No marble was shipped to the United States or to England, although there was a great demand in both countries therefor. Even now, prospects for marble shipments are none too bright. As an illustration of this it may be mentioned that this firm has had, since 1916, some 300 tons of marble lying on the docks at Piraeus awaiting shipment to New York. Tentative arrangements were in 1919 made from New York for shipping this consignment to America on an American vessel at $7.50 per ton freight, but upon the approach of the steamer its Piraeus agents demanded a minimum-freight payment of $125 per ton. This, with other expenses, makes the freight cost so much greater than the value of the commodity that it is feared that a long time must elapse before marble can be profitably shipped from Greece.

The following statement illustrates the production of marble and sales during 1918:

	Volume (cubic meters).	Weight (tons).
White Pentelic marble (quantity produced)	99	297
Sales in Greece:		
White and blue Pentelic	503	1,509
Mani (red)	43	129
Tinos (green)	3	9
Syra	11	33
Skyros	20	60
Total sales	580	1,740

[28] Annual report on commerce and industries for 1918 for the Kingdom of Greece, June 16, 1919.

[29] Figures not in agreement with table above.

GUATEMALA.

In 1916 a considerable quantity of marble was entered at the customs district of New York [30] for immediate consumption from Guatemala, although the general imports for that year did not show this material. The producing locality is near the village San Rosalia, in the hills northwest of Zacapa.

It is stated [31] by W. M. Strachan, trade commissioner, that the marble obtained from this quarry is pure white, and that the deposit is connected with the International Railways by a branch 10 miles long, which gives access to both the Caribbean Sea and the Pacific Ocean. The quarry is operated under concessions which provide for free entrance of machinery and no export tax on marble. In return the company gives the Government 10 per cent of any dividends declared. The railroad has given the quarry company a special rate for 50 years. In 1918 a considerable quantity of marble awaited shipment, but ocean rates were prohibitive. Before the war the United Fruit Co. quoted a rate of $5 a ton to New Orleans, New York, or Boston. The Mallory line and the Wood line gave a very low rate of $2.50 a ton, as the boats brought down coal for the railroad, and were glad to have the stone as return cargo. The railroad is now burning oil over its entire length, and this method of cheap transportation is cut off. The marble is used locally, the natives hewing out the stone and making tombstones and slabs for washboards.

PRICES OF FOREIGN MARBLES.

The following statement, published in the June, 1919, numbers of both the Monument Reporter and Stone, indicates the extent to which the prices of foreign marbles sold in the United States were affected during the war:

The lack of shipping during the war, the embargo on many lines of imports, and the shortage of labor in the European quarries naturally reduced the stock of foreign marbles held in this country. It gave an opportunity for the architects to become more familiar with the admirable decorative marbles that are found in this country, but unfortunately the suspension of building activity caused a moderate demand only. Dow's Daily Service Reports take up the question of foreign marbles. The building pulse, says a recent report, is being reflected by the movement for decorative interior materials. Various authorities have various views on price trends, particularly on foreign marbles. Current stocks are unquestionably low, but there are now on the ocean fine Italian and Belgian marbles, sufficient to keep the market well supplied, according to C. D. Jackson, of C. D. Jackson & Co., who says they are selling black and gold Italian marble as low as $6.70 for firsts, $6 for seconds, and thirds for $5.50.

The highest authorities on the marble situation show, however, that these advances have been made in marble prices since the time that war began to affect the Italian marble quarries, and that the marble situation here is undergoing the same transition with regard to price trend as are other building materials and commodities. White-veined Italian marble, familiar to commerce, has advanced 120 per cent; black and gold, 100 per cent on both first and inferior qualities; Blanco P, 100 per cent; Paonazzetto, 100 per cent; Botticino, 115 per cent; Travertine, 100 per cent; and Travernelle, 120 per cent. These advances were effective when there was scarcely any demand for interior marble in this country. To-day, with demand constantly increasing, the price trend will be toward the higher level, especially since Italian labor costs also

[30] U. S. Geol. Survey Mineral Resources, 1916, pt. 2, pp. 1009–1010, 1919.
[31] Stone, March, 1919.

have been advanced, and that the effort is to keep prices stable as long as it is possible to do so.

Labor on marble work offsets these price advantages, for in this section of the country the labor wage advances to marble workers have not exceeded 60 per cent.

LIMESTONE.

GENERAL STATISTICS.

The value of the limestone produced in the United States in 1918 increased $3,189,627 (nearly 7 per cent), but the quantity decreased 9,613,300 short tons (15 per cent). The total output for 1918 was 53,868,200 short tons, valued at $49,453,006, and represented 79 per cent of the quantity and 60 per cent of the value of all stone quarried in the United States in that year. The average price was 92 cents a short ton in 1918, which was 19 cents more than in 1917 and 31 cents more than in 1916.

PRODUCTION BY STATES.

Forty-five States produced limestone in 1918. Hawaii, reporting limestone sold to sugar factories, was added to the 1917 list.

Of the total producing States, 23 increased in value of output—Mississippi and Nevada, which reported production of limestone for the first time in 1917, showed increases of 20 per cent and 203 per cent, respectively, in 1918. Mississippi's output was for agriculture and that of Nevada for flux and for sugar manufacture. Maine, selling a small quantity of limestone to paper mills, also showed a considerable increase in value of output. The other States that increased in value of output reported gains ranging from 0.8 per cent in California to 63 per cent in New Jersey, New Jersey's stone being sold principally for flux. Michigan, Pennsylvania, and Ohio each showed increase in value of over $1,500,000. The principal increase in Michigan was for flux, which increased in quantity and value. In Ohio flux and crushed stone increased in value but decreased in quantity. In Pennsylvania flux showed large increase in value but decrease in quantity. For Alabama, Arizona, Colorado, Georgia, Massachusetts, Michigan, New Jersey, New York, Ohio, Pennsylvania, Tennessee, Vermont, Washington, West Virginia, and Wyoming the figures for value represent record values although not in all cases record production.

The decreased output shown by the remaining States ranged from 3 per cent to 83 per cent, and with the exception of the large decrease in the output of building stone in Indiana, the decrease was accounted for in greater part by the decrease in the production of crushed stone.

There were 11 States whose value of output was in excess of $1,000,000 in 1918. States whose product was valued at more than $2,000,000 were, named in order of rank, Pennsylvania, Ohio, Michigan, New York, Illinois, and Indiana. In 1917 Michigan ranked fifth and Indiana third and Illinois sixth. Michigan, Ohio, Pennsylvania, and New York showed gains, respectively, of 56 per cent, 29 per cent, 16 per cent, and 11.5 per cent; whereas, Illinois and

Indiana showed losses of 10 per cent and 37 per cent, respectively. The total number of active operators in 1918 was 1,190, a decrease of nearly 30 per cent in two years. Most of the small quarries were closed.

Value of limestone sold in the United States, 1914–1918.

State.	1914	1915	1916	1917	1918

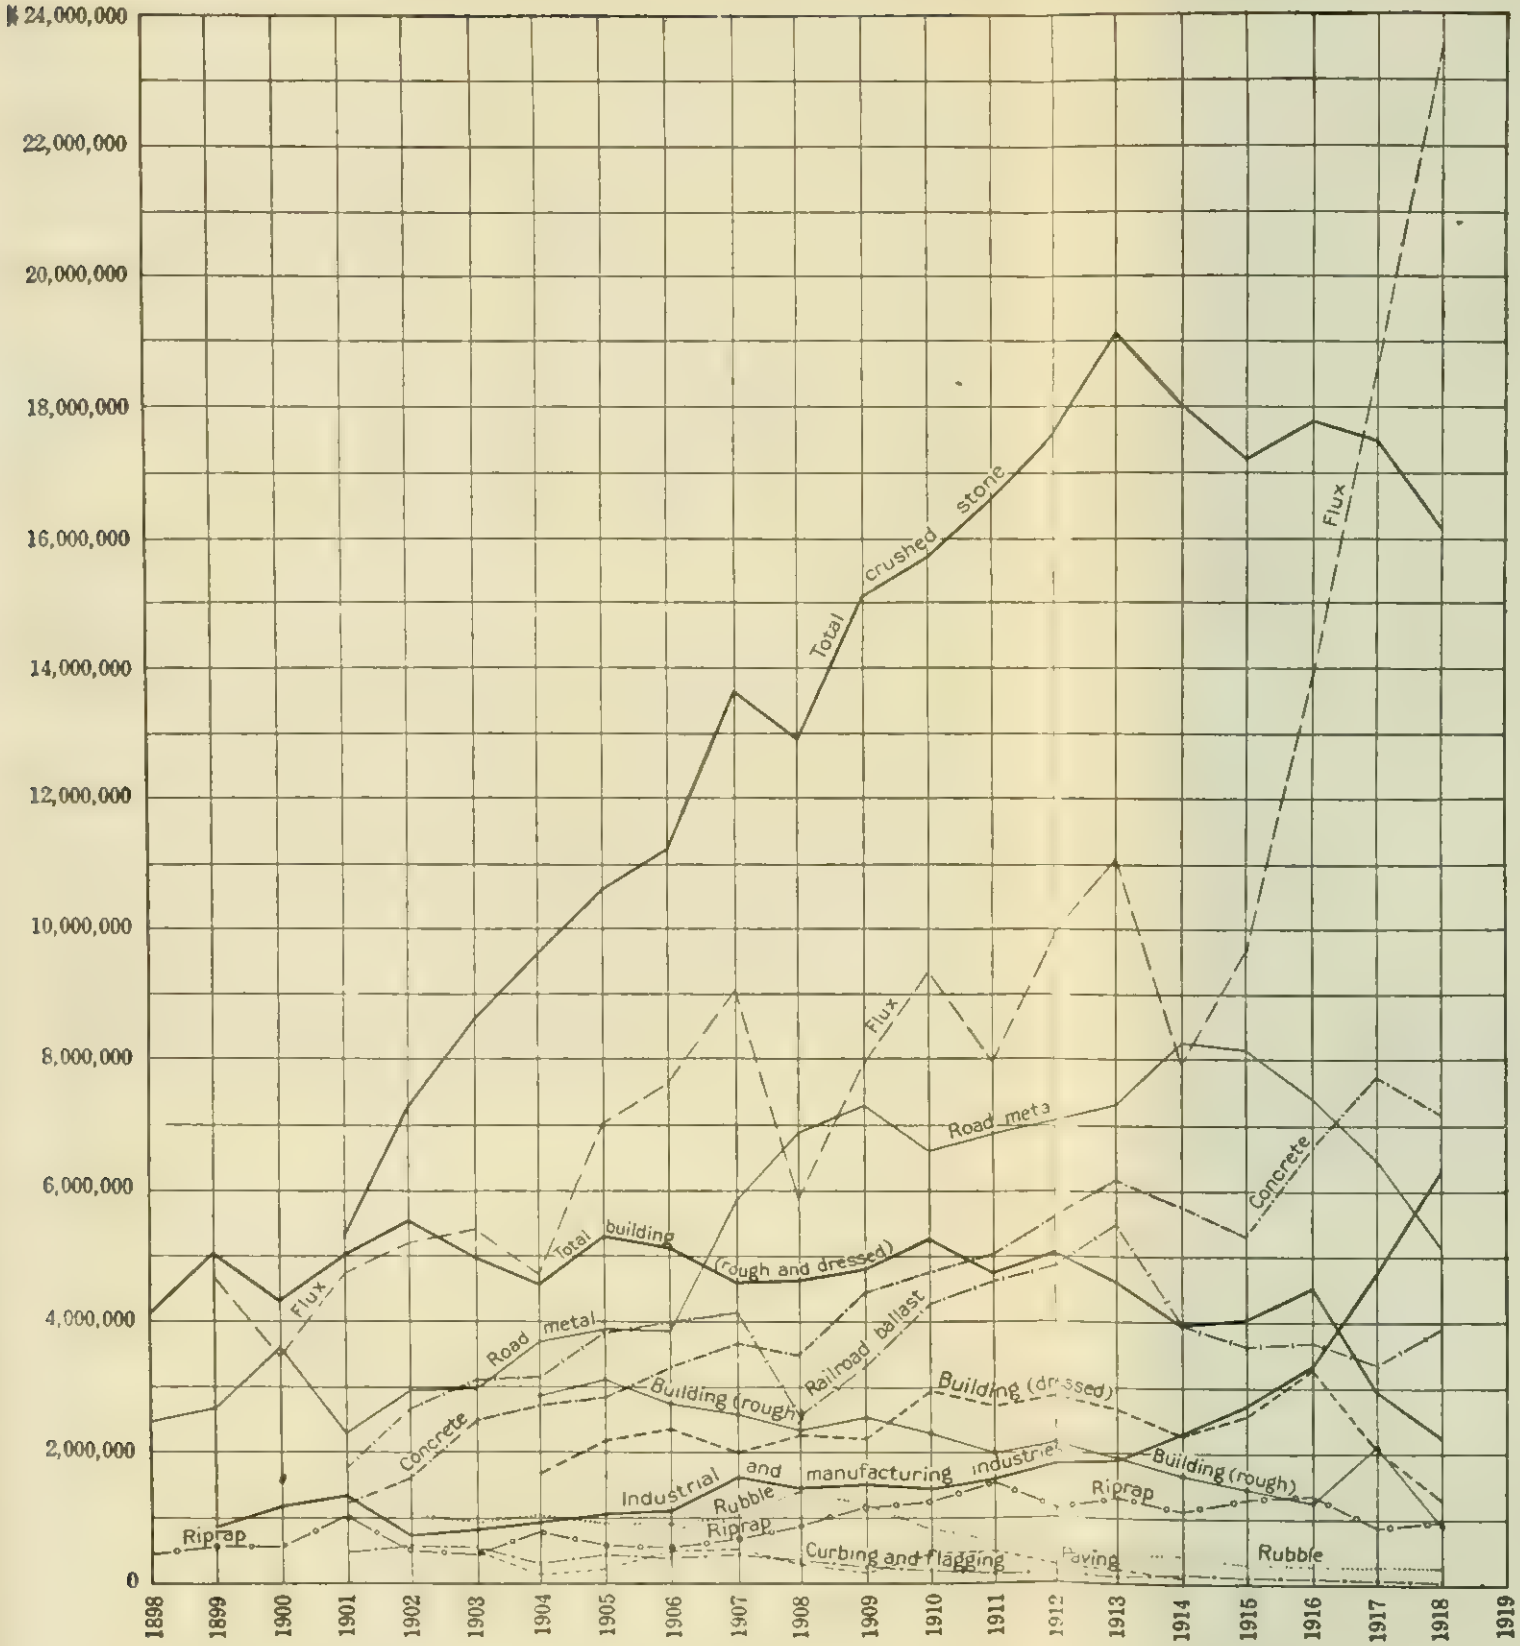
PRODUCTION BY USES.

The table on page 1253 shows the production of limestone in 1917 and 1918 according to uses, and Plate XV illustrates the changes in sales of the principal products of limestone since 1898. In the table the quantities are given in the customary units used in the trade, and also in approximate short tons for purposes of comparison and for expressing the entire quantity.



VALUE OF LIMESTONE SOLD IN THE UNITED STATES, 1898-1918, ACCORDING TO USES.

Limestone sold in the United States in 1917 and 1918, by uses.

Use.	1917		1918

Other uses [c].....do....	1,095,952	858,425	1,216,633	1,378,676
Total (quantities approximate, in short tons).	63,481,500	46,263,379	53,868,200	49,453,006

[a] Partly estimated.
[b] Paving blocks and flagging included in curbing.
[c] Includes stone sold as a filler for asphalt, paint, rubber, soap, and other material; stone sold for the manufacture of basic magnesium carbonate; stone sold to alcohol works and calcium carbide works; dolomite sold for use in making refractory products; stone sold for chicken grit and other products.

The production of limestone for riprap, agriculture, and for use in alkali works and a few other industrial and manufacturing uses increased in both quantity and value in 1918, but the increase in quantity for these purposes was not sufficient to offset the large decrease in building, rubble, crushed stone, and flux, although the increase in the price of all products brought the total value up to an amount greater than the value in 1917. In the following tables, showing the value of limestone by States and uses in 1917 and 1918, the quantity and value is given for all products in 1918, and such quantities as are available have been added to the figures of value for 1917 as published in the report for that year.

Limestone sold in the United States in 1917, by uses.

[b] Value of 53,868,200 short tons. [a] Included in "Undistributed."

The figures in the foregoing tables represent only the quantity and value of limestone sold or used as such by the producers. In addition large quantities of limestone are used in the manufacture of Portland cement and lime and a small quantity is used in the manufature of natural cement. As these products are largely manufactured by the companies quarrying the stone, and as the values of the manufactured products are given in other chapters of Mineral Resources, the quantity and value of the raw material is excluded from the preceding tables of this chapter to avoid duplication. The quantities of limestone quarried for these uses are approximately as follows:

Limestone used in certain industries in 1915, 1916, 1917, and 1918, in short tons.

	1915	1916	1917	1918
Portland cement (including limestone and some "cement rock")	24,095,355	23,323,220	24,640,230	17,658,700
Natural cement (cement rock)	153,060	158,054	102,260	67,300
Lime	7,179,358	7,685,723	7,194,000	6,400,000
	31,427,773	31,166,997	31,936,490	24,126,000

Thus the total quantity of limestone used for all purposes in 1918 amounted to nearly 78,000,000 short tons, compared with 95,000,000 short tons in 1917.

Closely associated with limestone in commercial usage as well as in chemical consumption and mode of occurrence is calcareous marl. A rough estimate of the quantity of marl used in manufacturing Portland cement in 1918 is 1,100,000 short tons. No data for estimating the cost of production are available. In addition about 98,694 short tons of marl, valued at $261,082, was produced and used in agriculture.

BUILDING STONE.

The limestone sold for use as building stone in 1918 amounted to 3,698,035 cubic feet, valued at $2,266,654, an average price of 61 cents a cubic foot ($7.30 a ton). This was a decrease, as compared with 1917, of 4,783,475 cubic feet (56 per cent) in quantity, $1,848,712 (45 per cent) in value, and 12 cents in average price per cubic foot.

In 1917 limestone as building stone represented 1 per cent of the total quantity of all limestone sold and 9 per cent of the total value, and in 1918 it was less than 0.6 per cent of the total quantity and 4.5 per cent of the total value. The principal districts in which building limestone is produced are the Bloomington-Bedford, in Lawrence and Monroe counties, Ind., and the Carthage, in Jasper County, Mo. A statement of the output and trade conditions of these districts follows.

INDIANA.

PRODUCTION.

The effect of the war on an important branch of the building-stone industry in 1918 was strikingly shown by the greatly reduced sales of Indiana oolitic limestone in the Bedford-Bloomington district, Ind.

The total value of Indiana oolitic limestone sold in 1918 was $1,961,154, a decrease, compared with 1917, of $1,422,956, or 42 per cent. This value was the lowest since 1904, when the stone sold was valued at $1,643,974.

Indiana oolitic limestone quarried and sold in Lawrence and Monroe counties, Ind., 1913–1918.

[a] Revised.
[b] Includes riprap, rubble, crushed stone, furnace flux, and stone sold to glass works and for agriculture.

In 1918, as in previous years, almost the entire value (93 per cent) was represented by building stone, whose total quantity was the smallest since figures showing quantity have been collected by the Geological Survey. The large decrease was due to railroad embargoes, scarcity of labor, and curtailment in building for all except war purposes.

In recent years the value of the Indiana oolitic limestone used for building has represented large percentages of the total value of limestone used for building in the United States, 69 per cent in 1913 and 1914; 72 per cent in 1915; 74 per cent in 1916; and 79 per cent in 1917. The quantity in 1916 was 77 per cent of the total quantity of limestone used for building and in 1917 nearly 80 per cent.

In 1916 this stone represented 34 per cent and in 1917 more than 38 per cent of all kinds of building stone sold in the United States.

Twenty-four plants in the Bedford-Bloomington district reported sales of stone in 1918, nine less than in 1917. Three of the plants reported no sales of building stone, their output being confined to crushed limestone, and six plants reported sales amounting to 291,819 cubic feet from stock on hand, their quarries being closed during the year. Two quarrying firms reported their quarries to be idle, their sales consisting of stock from other quarries.

The total quantity of building stone sold in 1918 was 2,701,745 cubic feet, valued at $1,820,167, a decrease, compared with 1917, of 60 per cent in quantity and 44 per cent in value, the average price increasing from 47 to 67 cents a cubic foot. Rough blocks and rough sawed stone amounted to 1,639,443 cubic feet, valued at $618,281, in 1918, a decrease of more than 67 per cent in quantity and 66 per cent in value, for the price per cubic foot rose from 31 to 38 cents. Dressed or manufactured stone amounting to 1,062,302 cubic feet, valued at $1,201,886, decreased nearly 40 per cent in quantity and more than 25 per cent in value, for the price per cubic foot increased from 92 cents to $1.13.

The quarrymen reported decreases of 10 to 35 per cent in their shipments, increases in cost from 25 to 60 per cent, increases in wages of 50 per cent, and increased cost of supplies of 100 per cent. Prices increased from 15 to 40 per cent. One quarryman reported that prices were practically the same as in 1917 until the later part of the season.

The range of prices in the district in 1917 and 1918, as reported by the quarry companies and the milling companies, was as follows:

Prices of Indiana oolitic limestone per cubic foot in 1917 and 1918.

Quarries.

The quality of the stone, the size of the blocks, and the amount of dressing regulated the price per cubic foot. The highest prices reported by the quarry companies are those of firms that milled their stone.

The mill owners of this district who buy rough stock made reports of adverse conditions similar to those made by the quarrymen. Business fell off from 33 to 66 per cent. Prices increased 15 to 75 per cent, although one company said the prices were but little higher than they were in 1917, and one company reported that the increase took place in the latter part of the year. The cost of the rough blocks was reported by some companies to be the same as in 1917, but by other companies to have increased from 25 to 40 per cent. According to the reports the cost of operation increased from 15 to 100 per cent, including increased cost of labor ranging from 29 to 130 per cent and increased cost of supplies from 25 to 50 per cent. Building stone was supplied only for buildings where investment was not considered, such as school buildings, hospitals, churches, asylums, and Government buildings. The outlook for 1919 was reported to be good, unless prospective builders refrained from giving contracts on account of the necessarily high prices. The quantity

and value of the finished stone sold by the mill operators in 1918 was 624,736 cubic feet, valued at $647,851. In 1917 this product was reported to be 1,471,101 cubic feet, valued at $1,788,405, which would represent a decrease in 1918 of more than 57 per cent in quantity and nearly 64 per cent in value. The average price in 1917 was $1.22 per cubic foot and in 1918 it was $1.04. In 1917 the figures of the milling operators included those of the Ingalls Stone Co. and the South Side Stone Co., but in 1918 the Ingalls Stone Co. took over the quarries of the Indiana Limestone Co., and the National Stone Co. absorbed the South Side Stone Co. These changes prevent any good comparison for the two years. The sales reported by the mill operators include 29,989 cubic feet, valued at $18,062, sold for monumental stone, the remainder being building stone. The combined value of the quarry and milling industry in 1917 was $5,172,515, and in 1918 $2,609,005, a decrease of 50 per cent.

SHIPMENTS TO DIFFERENT STATES AND TO CANADA.

In 1917 shipments of stone from the Bedford-Bloomington district were made to 43 States and to Canada. In 1918, in spite of railroad embargoes and curtailment of building work, shipments of building stone were made to 38 States and to Canada. California, Maine, New Hampshire, New Mexico, and Oregon, which received a total of 77,313 cubic feet in 1917, received no shipments of this stone in 1918. Twenty-four other States showed a decrease in shipments which ranged in the principal States from 6 per cent in Iowa, 26 per cent in Nebraska, and 35 per cent in Massachusetts to 50 per cent in Michigan, 51 per cent in Illinois, 56 per cent in Missouri, 58 per cent in Ohio, 65 per cent in Wisconsin, 67 per cent in North Carolina, 78 per cent in Pennsylvania, and 88 per cent in New York. The large shipments reported as made to points in Indiana, the leading State, are due in part to duplication, as stone that was sold by the quarry companies to mill companies in the Bedford-Bloomington district was counted twice. In 1917, after the total quantity shipped by milling companies was deducted, Indiana retained the lead by a large margin; whereas in 1918 the amount of stone which remained in the State (387,979 cubic feet) was slightly less than the amount shipped to Illinois, although Illinois showed a decrease of 51 per cent. Of the States showing increased shipments, the District of Columbia received the largest quantity of stone, 197,354 cubic feet, and increased 15 per cent; Minnesota received 96,278 cubic feet, and increased 11 per cent; Kentucky received 68,320 cubic feet, and increased 293 per cent. The other increases were Arkansas, 150 per cent; Colorado, 8 per cent; Connecticut, 44 per cent; Delaware, 253 per cent; Florida, 200 per cent; Kansas, 20 per cent; Mississippi, 436 per cent; Oklahoma, 26 per cent; and South Carolina, 68 per cent. All the increases except those in Colorado and Wyoming were confined to near-by and Eastern States. Eight States and Canada received shipments of more than 100,000 cubic feet in 1918, whereas 11 States and Canada were credited with more than that quantity in 1917. Notwithstanding the war, only 18 per cent less of the Indiana oolitic limestone was shipped to Canada in 1918 than in 1917.

Indiana oölitic limestone shipped to different States and Canada in 1917 and 1918, in cubic feet.

MINOR PRODUCTS.

In 1918 the quantity of stone which was reported as sold for other than building stone was 221,078 tons, valued at $140,987, and of this quantity 103,348 short tons, valued at $50,560—nearly 50 per cent of the quantity—was sold to iron furnaces and smelters, the open-hearth steel plants receiving 74,978 short tons and the smelters practically all the remainder; 37,426 short tons, valued at $27,546, was sold as ground limestone for agricultural purposes, and the remaining 80,304 tons, valued at $62,881, was sold as riprap, as crushed stone, and as material for glass factories and sugar refineries. A quantity of stone from this district was also used in the manufacture of cement and of lime, but is not included in these figures.

MISSOURI.

Missouri, which ranks next to Indiana in the production of limestone for building and which showed gains of 17 and 25 per cent, respectively, in 1915 and 1916 and a loss of 48 per cent in 1917, showed a further loss (11 per cent) in 1918. The production of this State is practically confined to the district at Carthage, Jasper County, part of whose output is considered as marble and part as limestone. The total production of this district is shown in the following table:

Limestone and marble sold at Carthage, Jasper County, Mo., 1913–1918.

Year.	Number of producers.	Building stone (rough and dressed).		Monumental stone (rough and dressed).[a]		Curbing.	Flagging.	Rubble.	Other.[b]	Total value.
		Quantity (cubic feet).	Value.	Quantity (cubic feet).	Value.

Percentage of increase or decrease	.....	−24.5	−20.8	−47.0	−45.9	.....	−32.9	+76.1	+128.9	−13.3

[a] Prior to 1916 included under "Other."
[b] Includes stone used for monumental work (prior to 1916), crushed stone, stone sold to glass factories, blast furnaces, sugar factories, etc.
[c] Curbing included in flagging; rubble includes riprap.
[d] Represents 33,875 short tons of stone in 1917; 45,677 short tons in 1918.
[e] Represents about 70,600 short tons in 1917; about 70,820 short tons in 1918.

The total quantity sold in this district in 1918 for all purposes was practically the same as in 1917, although the value of the output decreased 13 per cent. The total sales in 1918 were 70,820 short tons, valued at $339,898; in 1917, 70,600 short tons, valued at $392,443.

Although the Carthage district ranks next to the Bedford-Bloomington district, Indiana, its output of building stone was only about 1 per cent of that of the Indiana district in 1918. The quantity of building stone reported is the smallest since statistics showing quantity have been compiled by the Survey, and the value is less than that of any preceding year except 1913 and 1914.

Of the total output of the district in 1918, 263,272 cubic feet (about 21,770 short tons), valued at $271,216, was high-grade building and monumental stone. The output of this class of stone in 1917 was 363,723 cubic feet (about 30,000 short tons), valued at $361,220, a decrease of 27 per cent in quantity and 25 per cent in value for 1918. The stone sold for building in 1918 amounted to 236,885 cubic feet, valued at $239,418, a decrease of 25 per cent in quantity and 21 per cent in value. These decreases in percentages are strikingly less than corresponding decreases in the Bedford-Bloomington district of Indiana, which were 60 per cent in quantity and 44 per cent in value. The average price per cubic foot for building stone was $1.01 in 1918, 5 cents more than in 1917. Of the building stone sold in 1917, 93,964 cubic feet, valued at $142,061—$1.51 per cubic foot—was

dressed stone, whereas in 1918 the dressed stone reported as sold amounted to only 37,861 cubic feet, valued at $71,760—$1.90 per cubic foot. This decrease of 60 per cent in quantity of dressed stone sold tended to reduce the total value for the district. The rough building stone decreased from 219,940 cubic feet, valued at $160,350—73 cents per cubic foot—to 199,024 cubic feet, valued at $167,658—84 cents per cubic foot.

The stone sold for monumental work, which amounted to 26,387 cubic feet, valued at $31,798, decreased 47 per cent in quantity and 46 per cent in value. The average value was $1.17 in 1917 and $1.21 in 1918. Stone classified by the quarrymen as marble and included in the total amounted to 110,011 cubic feet, valued at $131,023.

Eight companies, one more than in the last six years, reported operations in 1918. They were the Carthage Marble & Building Stone Co., Carthage Marble & White Lime Co., Carthage Quarry Co., Consolidated Stone & Marble Co., the Missouri Quarries Co., the Spring River Stone Co., the Carthage Crushed Limestone Co., and the Independent Gravel Co., all of Carthage. The statistics given do not include the value of the rough stone sold by the quarrymen for crushing; the value given for this stone is its value after crushing. The producers that made statements regarding trade conditions in 1918 reported that business was poor and unsatisfactory, with little demand, and labor scarce and high, costing 25 per cent more than in 1917. Supplies were also reported as 25 per cent higher. The principal trade change reported was the taking over by the Missouri Quarries Co. of the quarry operated during the last few years by John Gill & Co.

The Carthage stone is sold principally in Missouri and the neighboring States of Arkansas, Oklahoma, and Kansas, but it has also been shipped west to California, east to New York, north to Illinois, Wisconsin, Michigan, Minnesota, and Canada, and south to Beaumont, Dallas, and Houston, Tex.

Though the building and monumental stone sold in the Carthage limestone district amounted to 70 per cent of the total value, nearly 65 per cent of the total quantity was sold in the form of broken, crushed, and pulverized limestone and a small quantity in the form of flagging. The total quantity of flagging, rubble, crushed, and pulverized stone sold in 1918 was 49,095 short tons, valued at $68,682; in 1917 it was 35,594 short tons, valued at $31,223, an increase of nearly 38 per cent in quantity and of nearly 120 per cent in value. The average price per ton of this stone in 1918 was $1.40; in 1917, it was 88 cents. Of the quantity stated above, 2,850 short tons, valued at $1,814, represented sales of rubble; 22,902 short tons, valued at $42,819, was stone sold to smelters, sugar factories, glassworks, powder mills, for agricultural use, and, as a substitute for whiting or chalk, or for filler, principally in the manufacture of soap, paint, putty, talc, and rubber; and the remainder was sold for flagging, concrete, and road metal.

OTHER STATES.

Kentucky.—In previous years the limestone quarried near Bowling Green, Warren County, Ky., has ranked in value of output of building limestone next to the Carthage, Mo., district. In 1918, however,

there were only two quarries in operation and the usual figures of local production are omitted. From reports of the owners of the idle quarries it seems doubtful whether operations will be resumed.

Alabama.—The quarries at Rockwood, Ala., which produce annually a considerable quantity of building stone, were taken over by the Government in July, 1918, and the output of building stone was greatly curtailed. It was the plan of the Government to operate these quarries in connection with the nitrate plants in that vicinity, the stone being of the desired quality and the supply practically unlimited. A considerable amount of new machinery was placed in the quarries and operations were begun on a large scale. The quarries were returned to the owners in March, 1919.

Florida.—The quarry near Miami, Fla., which has been operated extensively for building stone since 1914 was closed in 1918.

Minnesota.—In Minnesota the output of building stone in the two districts, Kasota, Le Sueur County, and Mankato, Blue Earth County, amounted to 85,998 cubic feet, valued at $95,615.

Building stone produced at Mankato and Kasota, Minn., 1916–1918.

Year.	Quantity (cubic feet).	Value.
1916	100,610	$91,323
1917	97,002	112,409
1918	85,998	95,615

These districts also produced 36,892 short tons of stone, valued at $28,745, in 1918 which was sold for rubble, riprap, crushed stone, and agricultural purposes. Building stone was also quarried in Minnesota in 1918 at Mantorville, Dodge County, and small quantities were reported from other localities.

Iowa.—The building stone reported from Iowa was principally from near Postville, Allamakee County; Anamosa and Stone City, Jones County; Keokuk, Lee County; and other scattered localities.

Kansas.—The localities in Kansas reporting building stone in 1918 were at Cottonwood Falls, Clark County; Silverdale, Cowley County; Emporia, Lyons County; Manhattan, Riley County; and other places of less importance.

Pennsylvania.—The building limestone reported from Pennsylvania was not confined to any one district, Howellville, Chester County, and Conshohocken, Montgomery County, furnishing the greater part.

OTHER USES.

PAVING, CURBING, AND FLAGGING.

The limestone sold for paving, curbing, and flagging has become an almost negligible part of the total production. The value of these products in 1918 amounted to less than 0.1 per cent of the total and showed a combined decrease of 44 per cent in value. Indiana, Kentucky, Missouri, and Wisconsin were the only States reporting output of these products.

RUBBLE.

The output of limestone for rubble, which has decreased continuously for the last nine years, decreased 62 per cent in quantity and 60 per cent in value in 1918. The principal producing States are Wisconsin, Missouri, and New York. Wisconsin and Missouri decreased, but New York showed an increase in value of output. This material is largely the product of the small local quarries and their abandonment on account of substitution of cheaper material has served to reduce the total output materially.

RIPRAP.

Limestone for riprap was one of the few limestone products to show increase in both quantity and value of output in 1918. The production was 1,118,109 short tons, valued at $969,276, a gain of 11 per cent in quantity and 13 per cent in value. Illinois, Indiana, Iowa, Kentucky, Minnesota, and Wisconsin were the principal producing States that increased in quantity and value of production of riprap; Kansas, Missouri, and Nebraska decreased in output. A large part of the riprap work carried on is under the direction of the United States Army Engineers for the improvement of the rivers and harbors. The railroad companies also use this stone for the protection of bridges and tracks.

CRUSHED STONE.

Continued decrease in the output of crushed limestone is shown in the following table:

Crushed limestone sold in the United States in 1916, 1917, and 1918, by uses.

Use.	1916		1917		1918	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.	Quantity (short tons).	Value.
Road metal	13,245,634	$7,416,984	9,273,282	$6,420,257	6,085,337	$5,177,501
Railroad ballast	8,088,673	3,650,647	6,579,905	3,394,455	5,509,911	3,901,682
Concrete	10,849,729	6,647,803	10,793,455	7,726,346	7,525,610	7,194,001
	32,184,036	17,715,434	26,646,642	17,541,098	19,120,858	16,273,184
Average price		0.55		0.66		0.85
Percentage of decrease			−17	−1	−28	−7

Of the decrease in total quantity of crushed stone 42 per cent (3,187,945 short tons) was in crushed stone for road metal; 14 per cent (1,069,994 short tons) for railroad ballast; and 44 per cent (3,267,845 short tons), for concrete. In 1917 these percentages were 72 per cent, 27 per cent, and 1 per cent, respectively. The only increase in either quantity or value of crushed stone sold in 1918 was in the value of the stone sold or used for railroad ballast, which increased 15 per cent ($507,187).

Thirty-four States reported crushed limestone in 1918, one less (Nevada) than in 1917. Of the States that produced more than 175,000 tons in 1918, 17 showed decrease in both quantity and value,

2 (Ohio and West Virginia) showed decrease in quantity and increase in value, and 1 (Tennessee) increased in both quantity and value. Ohio produced 21 per cent of the total crushed limestone in 1918, Illinois 15 per cent, and New York 12 per cent. Each of these States had an output of more than 2,000,000 tons.

FURNACE FLUX.

Limestone used as a flux in pig-iron furnaces, open-hearth steel works, and smelters represented nearly 50 per cent of the total quantity of limestone produced in 1918 and 48 per cent of the value, and for the second time exceeded crushed limestone in both quantity and value of output.

As was indicated by the condition of the iron trade during 1918, the quantity of limestone required by the furnaces during the year was less than in 1917. The output for 1918 amounted to 23,862,029 long tons, valued at $23,427,736, a loss of 1,712,117 long tons (6.7 per cent) in quantity but a gain of $4,748,523 (25.4 per cent) in value. This is the greatest recorded value for furnace flux but the greatest quantity sold was in 1917, during the time of greatest activity in the furnaces and smelters furnishing war material to the allied countries and to this country after its entrance into the war.

The following table shows the production of limestone for flux from 1913 to 1918.

Limestone sold for furnace flux, 1913–1918.

Year.	Quantity (long tons).	Value.	Average price.
1913	22,620,961	$11,103,989	$0.49
1914	15,298,756	7,890,369	.52
1915	18,998,723	9,672,347	.51
1916	23,623,508	13,946,882	.59
1917	25,574,146	18,679,213	.73
1918	23,862,029	23,427,736	.98

Besides the limestone, 16,904 long tons of marble, valued at $15,072, was sold for flux in 1917 and 55,012 long tons, valued at $84,899, in 1918. The production by States is shown for 1917 and 1918 in the tables on pages 1255 and 1259. Production in 1917 was reported from 36 States; in 1918 from 34 States, Arkansas and Kansas not reporting flux in 1918. Sixteen of the States showed decrease in quantity, although seven of these States showed increase in value.

The 18 States showing increase in quantity in 1918 showed also increase in value. Neither the increase nor the decrease was confined to any one section of the country. Pennsylvania continued to produce more than twice as much as any other State, although its output decreased nearly 12 per cent, whereas its value increased 19 per cent. Part of the apparent decrease of 281,694 tons in Alabama's figures was due to the inclusion, in 1917 and earlier years, under "other purposes" (refractories) of a quantity of stone used for the manufacture of "dead-burned" or sintered dolomite and used as a refractory in the open-hearth steel process. Ohio decreased in output of furnace flux 514,824 long tons (12 per cent) but increased in value $832,501

(33 per cent); West Virginia decreased nearly 20 per cent (333,962 long tons) in quantity but increased 13 per cent in value. Michigan and Illinois were the only two of the larger producing States that increased in production. Michigan's production increased 714,111 long tons (20 per cent) in quantity and $1,258,214 (77 per cent) in value. The average price for this State was 46 cents in 1917 and 67 cents in 1918. The greater part of Michigan's fluxing stone comes from Rogers City, Alpena County, and the large increase in 1918 followed an increase of 542,023 long tons in 1917 and continued a steady increase since 1913. Illinois, whose output of flux decreased in 1917, increased to more than 1,000,000 tons in 1918. New Jersey, Tennessee, Indiana, Arizona, and Washington, which made striking increases in 1917, continued to increase in 1918, whereas Maryland, after a decided increase in 1917, decreased in 1918.

In 1918 an attempt was made for the first time to separate the flux used by pig-iron furnaces, open-hearth steel plants, and smelters, and the result is given in the following table:

Limestone flux used in the United States in 1918, by uses.

Use.	Quantity (long tons).	Value.
Pig iron	15,197,900	$14,738,931
Open-hearth steel	5,134,828	5,997,005
Pig iron and open-hearth steel (not separated)	1,260,723	737,318
Smelters	1,066,282	897,861
Unspecified	1,202,296	1,056,621
	23,862,029	23,427,736

It will be seen that quarrymen were unable to tell the specific use of a little more than 5 per cent of the stone sold as a flux; also that approximately the same quantity was undivided between pig iron and open-hearth steel. It is hoped that a more complete division may be made in 1919. The total output of Arizona and Montana and the greater part of the output of California, Nevada, Texas, Utah, and Washington went to smelters. Pennsylvania furnished about 60 per cent of the stone reported sold to open-hearth steel works and West Virginia about 18 per cent. About one-third of the pig-iron flux was reported from Pennsylvania, one-fourth from Michigan, and about one-fifth from Ohio. The combined pig-iron and open-hearth flux was principally from the Illinois, Indiana, and New York quarries, and the unspecified material was from Illinois, Ohio, and Pennsylvania. It is possible that some of the stone reported as sold to open-hearth works was used as a refractory.

AGRICULTURAL LIMESTONE.

Pulverized limestone for agricultural use which from 1911 has showed a practically steady increase, recovered in 1918 from the slowing up of the industry during 1917 caused by difficulties of transportation and labor. The decrease of less than 1 per cent in 1917, followed by an increase of about 5 per cent in 1918, seems to show the permanence of this comparatively new industry. The output in

1918 was 1,091,918 short tons, valued at $1,626,292, a record production. The average price per ton was $1.49—19 cents more than in 1917. The burned lime sold for this purpose amounted to 391,047 short tons, a decrease of 20 per cent in 1918, and 34 per cent less than the output in 1911. The relations between sales of pulverized limestone and burned lime for agriculture are shown in the accompany-

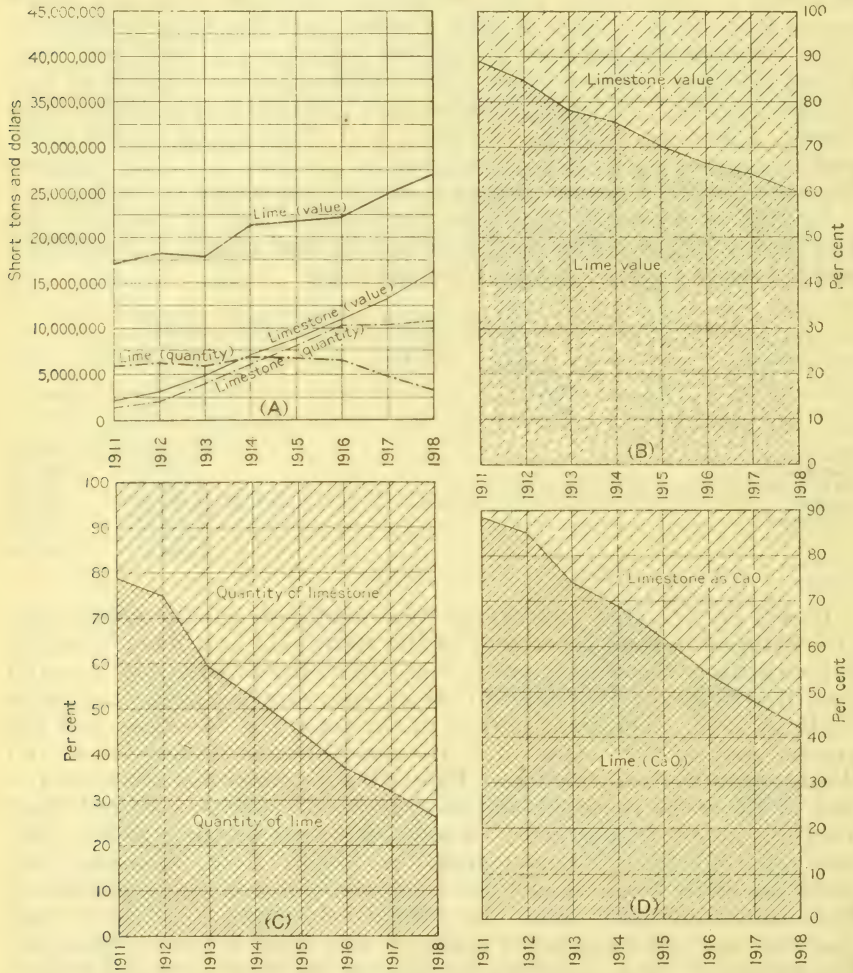

FIGURE 114.—Relations between sales of pulverized limestone and burned lime for agriculture, 1911–1918: A, quantity and value; B, percentages of total value; C, percentages of actual quantity; D, percentages of quantity in terms of calcium oxide (CaO).

ing table and in figure 114. In examining figure 114, D, however, it should be borne in mind that not all of the calcium oxide in limestone may be available for rapid reaction in the soil, as only that portion finer than 60–80 mesh can be considered equivalent to burned or hydrated lime in rapidity of reaction, whereas some of the agricultural limestone sold contains a considerable percentage of coarser grained material.

Lime and pulverized limestone sold for use in agriculture, 1911–1918.

Year.	Lime.		Limestone.	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.
1911	596,664	$1,714,386	174,290	$205,006
1912	604,607	1,852,530	200,000	311,702
1913	590,229	1,798,566	408,627	493,718
1914	684,348	2,139,444	615,197	688,961
1915	673,260	2,163,874	810,399	893,530
1916	613,564	2,224,058	1,043,876	1,109,208
1917	488,297	2,475,731	1,040,248	1,352,397
1918	391,047	2,698,848	1,091,918	1,626,292
Average price per ton		6.90		1.49
Increase or decrease (per cent)	−19.9	+9.0	+4.9	+20.3

The pulverized limestone industry was less affected by the shortage of fuel than the lime industry, and the present high price, the scarcity of fuel, and the increased cost to the producer may prevent the burned lime from resuming its normal for a considerable time. The total quantity of limestone quarried in 1918 for use by farmers was about 1,870,000 tons, whereas in 1917 it was about 2,000,000 tons and in 1916, 2,270,000 tons. In addition to pulverized limestone and burned lime, 78,232 tons of calcareous marl, valued at $203,500, was sold for this use.

In 1918, as in 1917, Illinois was the leading State in quantity of output of ground limestone for agriculture, but Pennsylvania, the third in quantity, stood first in value. Michigan ranked second in quantity. Illinois and Michigan increased in both quantity and value of output, and Pennsylvania decreased in output with increase in value. New York showed decided decrease in both quantity and value.

The agricultural departments of many of the States as well as the United States Department of Agriculture are interested in the testing of both lime and limestone for use on soils, and in many communities the farmers' organizations have crushers and produce the pulverized limestone cheaper than it can be purchased.

SUGAR FACTORIES.

The limestone sold to sugar factories fluctuates in quantity probably more than any other stone product, and the fluctuation does not always conform to the increase or decrease in the production of sugar. The stone sold to sugar factories is burned by them into lime at such times as need arises, and limestone purchased for this purpose may or may not be used in the same year in which it is sold. After an increase of nearly 44 per cent in 1917, the limestone purchased by sugar factories decreased 95,057 short tons (nearly 18 per cent) to 435,555 short tons in 1918. The burned lime sold for this use decreased from 47,546 short tons to 36,494 short tons (23 per cent). This followed an increase of 117 per cent in 1916. The marked increase in 1917 for both lime and limestone was in keeping with the demand for sugar to supply both the needs of the United States and those of foreign countries. The demand still continued in 1918, but

the stone reported as sold to the factories apparently did not conform thereto.

The following table shows the limestone and lime used by sugar factories, 1915–1918:

Limestone and lime sold to sugar factories, 1915–1918.

Year.	Limestone.		Lime.	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.
1915	394,122	$381,038	34,025	$230,368
1916	369,028	392,694	21,923	118,572
1917	530,612	666,138	47,546	381,746
1918	435,555	649,589	36,494	314,748

In 1917 California furnished the largest quantity of limestone for refining sugar, closely followed by Colorado and Wyoming. In 1918, however, Wyoming produced 89,947 short tons, which, although a decrease, exceeded Colorado's production of 77,751 tons. California produced 43,561 tons.

GLASSWORKS.

The limestone sold to glassworks in 1918 amounted to 202,211 tons, valued at $332,744, a decrease of 90,941 tons (31 per cent) in quantity, but of only $11,735 (3 per cent) in value. The average price per ton in 1918 was $1.65; in 1917 it was $1.18.

The burned lime sold to glassworks in 1918 amounted to 34,051 short tons, valued at $265,855—a total value of $598,599 for limestone used in making glass. Pennsylvania, Ohio, Missouri, and West Virginia were the principal producing States.

PAPER MILLS.

The limestone sold to paper manufacturers in 1918 amounted to 100,247 short tons, valued at $117,829, practically the same quantity as in 1917 (101,305 short tons), but an increase of $22,247 (23 per cent) in value. The lime burned and sold for this purpose in 1918 amounted to 325,172 short tons, valued at $2,610,645, a decrease of about 9 per cent in quantity but an increase of 30 per cent in value. Pennsylvania, Michigan, and New York furnished most of the limestone and Pennsylvania, Massachusetts, Maine, New York, and Indiana most of the lime used for this purpose.

MISCELLANEOUS USES.

Limestone sold for miscellaneous purposes reported in the tables on pages 1256 and 1261 includes material produced in only one or two States by individual producers or in quantities too small for segregation. This class of stone represented about 6.4 per cent of the total quantity in 1917 and about 8.6 per cent in 1918. A detailed statement of this limestone by uses, as far as it is possible to publish a statement, is given in the following table:

Limestone sold for miscellaneous uses in 1917 and 1918.

Use.	1917		1918	
	Quantity (short tons).	Value.	Quantity (short tons).	Value.
Alkali works	3,124,026	$1,417,898	3,437,066	$2,263,821
Refractories	232,121	171,257	490,863	560,209
Whiting	34,983	75,326	43,011	196,944
Magnesia plants	73,214	89,189	90,989	126,255
Lime burners	59,387	31,736	79,100	65,705
Asphalt filler	30,408	125,648	20,512	52,701
Mineral wool	12,030	8,818	25,640	37,052
Carbonic acid works	(*a*)	(*a*)	22,355	36,868
Chicken grit	(*a*)	(*a*)	5,432	13,651
Chemical works	(*a*)	(*a*)	4,682	10,260
Powder works	(*a*)	(*a*)	7,724	8,376
Other uses *b*	644,419	356,451	425,325	270,625
	4,219,978	2,276,323	4,652,699	3,642,497

a Included in "Other uses."

b Includes stone sold for manufacture of calcium carbide, carbolic acid, nitrate of ammonia, and the purification of copper; for roofing, gravel, filter stone, artificial stone, and other uses not specified.

ALKALI WORKS.

More than 73 per cent of the stone classed as miscellaneous is represented by stone used by alkali works. In 1918 this use amounted to 3,437,066 short tons, valued at $2,263,821, an increase of 10 per cent in quantity and of nearly 60 per cent in value. The greater part of this stone is quarried by the alkali manufacturers, and 64 per cent of it in 1918 was from quarries in Michigan; most of the remainder was quarried in New York, Ohio, and Kansas, but smaller quantities were reported from Pennsylvania and Virginia. Burned lime amounting to 145,031 short tons and valued at $768,570, principally from Virginia, but also from West Virginia, Tennessee, Pennsylvania, and Massachusetts, was also reported as used by alkali works.

REFRACTORIES.

Dolomite or magnesian limestone for refractory use became an important limestone product during the war on account of the cessation of shipments of Austrian magnesite, for which it was substituted. Although it was known that domestic dolomite and the dead-burned or sintered product was used by steel companies long prior to 1914, it was not until that year that the production of a small quantity of sintered dolomite was reported, with the statement that its use was the same as that of magnesite. The quantity previously used was evidently small in comparison to that used since the beginning of the war, and was not reported as a separate item by the producers. Since then it has emerged from the experimental stage until in 1917 about 679,000 short tons, and in 1918 1,129,000 short tons, of dolomite was quarried for this purpose. The chief problem in perfecting this product was the calcining that would prevent slaking of the lime present. The latest and most successful method of doing this is the coating of the sintered product with fused clay or slag. The principal use of sintered dolomite is in granular form for bedding and for plastering walls, replacing granular calcined

magnesite. Processes for manufacturing it into bricks have been patented, and production of such bricks on a commercial scale may be expected.

Dolomite for refractory use is reported to the Geological Survey under two forms. Part is sold by the quarrying company to the manufacturer and is reported as raw stone; part is both quarried and dead-burned by the manufacturer and is reported as finished product. In order to express the total quantity of raw stone and the equivalent quantity of finished product, the table below gives each item as reported, supplemented by the calculated quantity of the other item.

The great increase in the recorded quantity of dolomite refractories sold in 1918 is in marked contrast to the small decrease in the output of open-hearth steel. The difference is due in part to inclusion of Alabama's output for the first time in 1918. This State's output had formerly been reported as flux for open-hearth steel furnaces, although it was burned before entering the furnace.

Dolomite sold for refractory use was reported as raw stone from Alabama, California, Illinois, Michigan, Ohio, and Pennsylvania; the dead-burned product was reported from Pennsylvania, New York, and Ohio.

Raw and dead-burned dolomite produced for refractory use in 1917 and 1918.

	Quantity (short tons).		Value.	Average price per ton.
	Raw.	Dead burned.		
1917.				
Quarried and burned by producers and reported as dead-burned dolomite		223,300	$2,376,633	$10.66
Equivalent raw stone (approximate)	446,600			
Sold by quarrymen to manufacturers of refractories. Reported as raw stone	232,421		171,257	.74
Equivalent dead-burned product (approximate)		116,210		
	679,021	339,510		
1918.				
Quarried and burned by producers and reported as dead-burned dolomite		318,896	4,097,819	12.85
Equivalent raw stone (approximate)	637,800			
Sold by quarrymen to manufacturers of refractories. Reported as raw stone	490,863		560,209	1.14
Equivalent dead-burned product (approximate)		245,431		
	1,128,663	564,327	4,658,028	

Dolomite for refractory purposes has been used in Europe with indifferent success. A considerable quantity of dolomite was, however, used for refractories in Great Britain during the war and W. W. Jones [32] at a meeting of the refractory materials section of the Ceramic Society, May 22–23, 1919, stated that during the last two and one-half years of the war 127,000 tons of raw dolomite and 410,000 tons of calcined dolomite had been used in Great Britain for munitions purposes.

[32] The Quarry, London, England, June, 1919, p. 164.

WHITING (CHALK).

Another product whose output has increased through the needs of war is the pulverized limestone used as a substitute for whiting and chalk. In 1916 the rough limestone reported as sold for the manufacture of whiting was 24,722 short tons, valued at $47,435; in 1917, it was 34,983 short tons, valued at $75,326; and in 1918, it was 43,011 short tons, valued at $196,944, an increase in 1918 of 23 per cent in quantity and of 161 per cent in value. This whiting was reported in 1918 from 10 States, Alabama, California, Connecticut, Florida, Illinois, Michigan, Missouri, Nebraska, Nevada, and Utah; in addition 28,815 short tons of pulverized marble ("marble flour"), valued at $86,619, was produced in 1918, a total of 71,826 short tons of whiting, valued at $283,563, sold during the year. In 1917 the total, including marble, was 58,276 tons, valued at $133,957, an increase in 1918 of 23 per cent in quantity and of 112 per cent in value.

The marble for this purpose was from Alabama, Georgia, Massachusetts, New York, and Tennessee. The greater part of this material was reported as sold for paint and putty filler, but it was also sold as a filler for soap, rubber, pottery, and other products which contain whiting.

The average price of the total output was $3.95 a short ton. The individual prices received, however, ranged from $1 to $10 a short ton, evidently because of differences in care of preparation. Some of the specially-treated material sold as high as $20 a ton.

The quantities of whiting reported as used in different industries are not accurately known. According to information received by the Shipping Board, manufacturers of rubber goods consumed about 35 per cent of the total importation of chalk in 1917. Individual companies, however, reported that this consumption was as high as 75 per cent. Accepting 35 per cent as approximately correct, the Shipping Board estimated that about 50 per cent of the total imports was consumed by the paint industries, 10 per cent by the putty trade, and about 5 per cent for other uses, including glazes for ceramic goods, manufacture of leather goods, manufacture of chemicals, molds, and cores in brass foundries, filler for paper, mild abrasives especially for cleaning plate, adulterant in various processes, base for picture molding, and insulators.

When the shortage of ships was becoming increasingly serious during the early part of 1918, the Shipping Board considered curtailment of imports of chalk to half their normal volume, which, because of its bulk, consumed considerable time in loading and unloading. This plan brought protests from many importers and consumers who stated that English chalk or whiting could not be adequately replaced by domestic substitutes. The small curtailment made, however, brought no complaints of shortage nor any vigorous search for superior deposits of domestic chalk then or even later when the steamship companies themselves decided to stop carrying chalk so as to save time. Evidently a sufficient surplus was in the country to bridge over the brief interval of shortage, or domestic whiting made by the extremely fine pulverizing of limestone and

marble was found adequate for use either alone or mixed with English whiting.

Consumers of imported whiting claimed that it was "amorphous"—a term which, to judge from microscopic examination, implied extremely fine crystalline particles accompanied by colloidal matter—whereas domestic whitings were "crystalline"—that is, of coarser grain and deficient in colloidal matter. Some domestic producers in 1918, however, claimed to be producing material of excellent physical properties, including pure white color, economical absorption of oil, good stretching power (in putty), and ability to take up more marble dust than English whiting. The increased use of domestic whiting tends to confirm these claims, although full confirmation will depend upon the demand in 1919, or since the removal of restrictions on imports. Much of the domestic production in 1918 was consumed in the Central States, but some was shipped to New York and probably other Atlantic ports. One producer shipped from Death Valley to cities in California.

A few producers have been very secret about their raw material and process of manufacture, but others have been very willing to give any information requested. That made as a by-product from the pure-white marble of the Georgia Marble Co., at Tate, Ga., contains between 98 and 99 per cent of calcium carbonate, the remainder being chiefly lime-magnesia silicate. The finest grade produced passed 100 per cent through a screen of 300 meshes to the inch and was used in 1918 chiefly as a rubber filler. In contrast to this, whiting manufactured by the Metro-nite Co., Milwaukee, Wis., contains 44.62 per cent of calcium carbonate, 35.65 per cent of magnesium carbonate, 19.58 per cent of calcium-magnesium silicate, and 0.15 per cent of moisture. Its finest grade will pass 100 per cent through a 225-mesh screen. Domestic whiting manufactured by P. W. Nelson (Inc.), Brooklyn, N. Y., contains 98.50 per cent of calcium carbonate, 0.10 per cent of magnesium carbonate, 0.18 per cent of silica, 0.79 per cent of iron oxides, 0.02 per cent of alumina, and 0.07 per cent of organic matter.

The requirements of whiting for most uses depend on its physical properties, chiefly color, extreme fineness of grain, and the presence of considerable colloidal matter, but no exact specifications for any use except the ceramic industries have been reported to the Survey. According to P. H. Bates,[23] of the Bureau of Standards, Department of Commerce, whiting for the ceramic industries must be very low in iron oxides, preferably not more than 0.05 per cent; its content of calcium carbonate should be about 99 per cent, although it may be as low as 98 per cent if the impurities are only silica and alumina; it must be very fine grained so that practically 100 per cent will pass a 150-mesh sieve. The fineness of whiting must be such that it will not settle instantaneously in water, but that part of it, about 30 per cent, will remain suspended for some time. The chemical requirements will rule out most of the limestones and even some of the white marbles of this country, but some of the white marbles of Vermont, which have proved suitable for the manufacture of optical glass, and

[23] Written communication May 7, 1918.

some from Georgia and Alabama, are quite satisfactory in chemical composition.

Mr. Bates also states that it is perfectly possible to prepare whiting from marble if the grinding is carried far enough and conducted with wet material. Perfectly satisfactory material has been produced in this way at the Bureau of Standards. Cost and care to reduce the material to suitable fineness without introducing impurities, particularly iron oxide, are the determining features.

Chemically precipitated calcium carbonate has also been suggested as a substitute for English whiting. Considerable quantities of such calcium carbonate have been made as a by-product from the manufacture of basic magnesium carbonate, but, at least prior to the war, the cost of drying it and keeping it free from impurities has prevented its competition for the whiting market. It doubtless contains considerable colloidal matter; in fact, one manufacturer stated that its absorption of oil, caused probably by the colloidal matter, was too high. A mixture of this chemically precipitated calcium carbonate with finely ground marble, however, should closely approximate English whiting in physical and chemical properties.

Some importers and consumers of whiting in their correspondence with the Shipping Board went so far as to state that there were no deposits of chalk in the United States and Canada. So far as the discovery of extensive high-grade deposits is concerned, this statement is essentially true. Extensive deposits occur, however, in the Cretaceous formations of the West-Central and Southern States and have been quarried by manufacturers of Portland cement, but they are of too low grade for the manufacture of whiting. The chalks of South Dakota, Nebraska, and Kansas contain from 88 to 95 per cent of calcium carbonate, the remainder being principally clay. Several analyses of chalks in southwestern Arkansas show calcium carbonate to range from 90 per cent downward. One analysis showing as much as 98 per cent of calcium carbonate has been reported, but there is no evidence that it represents the average of a workable deposit. The chalks of eastern Texas are essentially continuous with those of Arkansas and attempts to find deposits in them suitable for whiting are said to have failed. The Selma chalk which extends across Alabama and Mississippi is also generally of low grade.

Fresh-water deposits of finely divided calcium carbonate, called fresh-water marl, are also possible sources of suitable material, but they contain as a rule enough organic matter to darken their color. A few samples of unusually white material which may have come from such fresh-water deposits have been received by the Survey, and the suggestion has been made to the senders that it may prove suitable for whiting; but nothing further has been heard from them.

This country's participation in the war was hardly long enough to determine fully its resources of material suitable for whiting. The trend of the industry during 1917 and 1918, however, clearly demonstrated that, should imports be stopped, the country will depend far more on the careful preparation of ground marble and limestone than on the quarrying of chalk or fresh-water marl.

137536°—M R 1918—PT 2——81

The imports of chalk are shown in the following table, compiled from figures furnished by the Bureau of Foreign and Domestic Commerce, Department of Commerce:

Chalk, etc., imported for consumption, 1916–1918.

	1916		1917		1918	
	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.
Chalk, crude, not precipitated, or otherwise manufactured (duty free).....long tons..	133,188	$112,671	129,711	$126,605	83,933	$113,985
Ground or bolted (duty 0.1 cent a pound).....pounds..	.....	.....	1,195,955	6,241	241,752	5,829
Precipitated, for medicinal purposes (duty 25 per cent).....	.....	27,713	.....	29,980	.....	34,273
Forms of cubes, blocks, sticks, dishes, or otherwise, including tailor's, billiards, etc. (duty 25 per cent).....	.....	4,096	.....	6,563	.....	4,687
French, cut, powdered, washed, or pulverized (duty 15 per cent).....	.....	628	.....	222	.....	266
Manufactured, not elsewhere specified (duty 25 per cent).....	.....	249	.....	310	.....	617
Whiting and Paris white, dry (duty 0.1 cent a pound).....pounds..	2,308,726	9,952	4,054,622	22,485	2,446,180	16,949
Whiting and Paris white, ground in oil or putty (duty 15 per cent).....pounds..	28,334	972	37,230	2,879	14,282	1,904

The principal features of this table are the considerable decreases in the ground or bolted chalk, and of whiting and Paris white. The quantity of ground or bolted chalk decreased about 80 per cent in 1918, and the average price increased from about $10 a ton in 1917 to about $48 a ton in 1918. The whiting and Paris white decreased nearly 40 per cent in quantity and the average price increased from $11 a ton to nearly $14 for the dry material, and that ground in oil or putty decreased 60 per cent in quantity and the average price increased from about $155 a ton to $272 a ton in 1918.

Monthly returns from January to October, inclusive, 1918, showed that imports of crude or unmanufactured chalk were almost exclusively from England, a small quantity being credited to Denmark and a still smaller quantity being entered through Canada. Imports in February, March, April, and May averaged about double those of the other six months. Nearly three-fifths of the total quantity was entered at New York; Philadelphia received less than one-third; and Massachusetts most of the remainder. A small quantity was entered at New Orleans.

Imports of "chalk, ground, precipitated, etc.," also came almost exclusively from England, a small amount being credited to France and trifling sums to Japan, Switzerland, and Canada. Of the imports received during the first six months more than two-thirds of the value was entered at New York; St. Louis, Philadelphia, and Maryland were next in importance; and Chicago, Indiana, San Francisco, Porto Rico, Massachusetts, Hawaii, and Maine-New Hampshire received small amounts.

MAGNESIA PLANTS.

The dolomite quarried in Pennsylvania and Wisconsin and sold principally for the manufacture of basic magnesium carbonate used with asbestos in the manufacture of heat insulating material,

amounted in 1918 to 90,989 short tons, valued at $126,255, an increase of 24 per cent in quantity and 42 per cent in value.

LIME BURNERS.

Stone reported as sold to manufacturers of lime in 1918 amounted to 79,100 short tons, valued at $65,705, an increase of 33 per cent in quantity and of 107 per cent in value.

This is principally stone quarried in Ohio and shipped to Duluth, Minn., and stone quarried in Michigan and shipped to Niagara Falls, although sales of stone for this purpose were reported in Colorado, Illinois, Missouri, Pennsylvania, Utah, and West Virginia. In these States the stone was not shipped but was burned in the neighborhood of the quarry.

ASPHALT FILLER.

The decrease of 48 per cent in quantity of pulverized limestone sold for asphalt filler in 1918 may be accounted for by the greatly decreased activity of city street work in 1918. The States reporting stone for this purpose in 1918 were California, Illinois, Ohio, and Tennessee in almost equal quantity, and Connecticut, Minnesota, Missouri, New York, Pennsylvania, and Texas in smaller quantity.

MINERAL WOOL.

The stone sold for the manufacture of "mineral wool" in 1918 amounted to 25,640 short tons, valued at $37,082, an increase of 13,610 tons in quantity and of $28,264 in value. Mineral wool is manufactured from low-magnesium argillaceous limestone quarried near Yorktown, Delaware County, and Alexandria, Madison County, Ind., and is used as an insulating material, notably in refrigerators and fireless cookers.

CARBONIC-ACID WORKS.

The 22,355 tons of stone, valued at $36,868, reported as being sold to carbonic-acid plants was quarried in California, Florida, Nevada, and New York. Near Los Angeles, Calif., at one carbonic-acid plant the lime remaining after the carbonic-acid gas is driven off is sold for the manufacture of hydrated lime.

CHICKEN GRIT.

The limestone reported as sold for chicken grit in 1918 amounted to 5,432 short tons, valued at $13,651, and was from California, Illinois, Nevada, Ohio, and West Virginia. Marble, granite, and miscellaneous varieties of stone were also reported as sold for chicken grit, but the sales are not included here.

CHEMICAL WORKS.

California, Maryland, Missouri, and Washington reported stone sold to chemical works without specifying any particular product. The sales amounted to 4,682 short tons, valued at $10,260.

POWDER WORKS.

Limestone from Illinois, Missouri, and Pennsylvania was sold for use in powder works. The sales reported amounted to 7,724 short tons, valued at $8,376.

OTHER USES.

The largest item included under stone sold for other miscellaneous uses was stone used in calcium carbide works and quarried in Michigan. The remainder of the stone was sold for the manufacture of carbolic acid, nitrates, and ammonia; for the purification of copper; and for roofing gravel, filter stone, and other uses not specified.

WAR USES.

Although crushed limestone was the leading limestone product until 1917, it was displaced by stone for furnace flux during the war. The distribution of limestone with respect to blast-furnace districts was most fortunate and enabled the country to carry on the iron and steel industries at great speed. The demand for flux became so great that several companies that formerly quarried no stone for flux made this their main product.

The quantity of limestone used directly in the chemical industries amounted in both 1917 and 1918 to 5,000,000 short tons and besides this nearly 1,400,000 short tons of burned or hydrated lime was used—a total of about 7,500,000 tons of stone quarried. It has justly been said that limestone and lime are the complement of sulphuric acid as fundamental chemicals for the industrial world. These materials are used in more than 100 industries involving chemical processes, many of them very essential war industries. Little public attention, however, was attracted to so common a commodity as lime, and it may be a matter of some surprise to learn that early in 1918 there was a shortage of high-calcium lime in the Middle Atlantic States after our industries had adjusted themselves to a war basis. To help regulate the supplies of lime the United States Geological Survey cooperated with the National Association of Lime Manufacturers and the War Industries Board by preparing a map showing the location, relative size, kind of product (high calcium or high magnesium) and distribution of output by uses. This served as a basis for economy in transportation of fuel and finished product. It also showed most strikingly the discordance between the principal lime-producing centers and the areal extent of limestone formations. A reduced and simplified copy of this map accompanies the chapter on lime in the Mineral Resources volume for 1918.

Besides forming a basis for the expansion of established industries most essential to the war the limestone resources have met every new demand placed upon them. Some of the cyanamid plants to be established by the Federal Government were located first and the relation of location to certain important raw materials was considered afterwards. The limestone required for one of these plants amounted to 500 tons a day of stone containing 97 per cent of calcium carbonate ($CaCO_3$) within easy transportation distance. The necessary deposits were found—and incidentally a suspicion was confirmed that many published analyses were not representative. Quarries represented by analyses as consisting of nearly pure cal-

cite rock proved to contain sufficient dolomitic rock to render the quarrying of 500 tons a day of high-calcium stone utterly impossible. The need of accompanying analyses with adequate statements describing the areal extent, thickness, and variations in character of deposits and their relations to quarrying conditions is here apparent, and it is a regrettable fact that most commercial analyses of limestone or lime give no information on these points. Other calls for limestone or lime demand material of a certain degree of purity; as, for example, when the domestic manufacture of optical glass was being considered a call was made for limestone containing less than 0.05 per cent of Fe_2O_3, and very few analyses of quarried limestones could be found in which alumina and iron oxide were separately determined. The extraordinary growth of the use of limestone in the chemical industries, as well as the present trend in the purely geological study of sedimentary rocks, calls for more complete analyses than have ordinarily been made.

Domestic limestone and lime have also successfully replaced materials formerly imported. Some of these, like "Vienna lime," ("Wienerkalk") were imported in small quantities for special uses and have no appreciable effect on the quantity of lime consumed, although the demand for these small quantities may be urgent. One product, however, has been developed on a large scale and its manufacture shows promise of surviving the war period as a permanent industry; this is dead-burned or sintered dolomite, which has largely replaced foreign magnesite and has successfully competed with domestic magnesite as a refractory largely because of its geographic position. Its production is discussed on page 1277 under the head of refractories.

LITHOGRAPHIC STONE.

No production of lithographic stone was reported to the Survey in 1918, and no stone was imported for lithographic work during the year. The quarry at Brandenburg, Ky., which so far has furnished all the commercial domestic lithographic stone used in the United States, was operated irregularly for crushed stone, for hones, and for other products of limestone, the owner having joined the army in the spring of 1918 and the sales office being closed.

SANDSTONE.

GENERAL STATISTICS.

The production of sandstone in the United States has decreased each year since 1903, except in 1909, 1913, and 1914. The sales in 1918 amounted to 2,858,100 short tons, valued at $4,529,298, a decrease of 26 per cent in quantity and about 18 per cent in value from the output in 1917. In 1918 as in 1917 sandstone represented 4 per cent of the total quantity of all stone sold, whereas the value in 1917 was 6.7 per cent and in 1918 it was 5.5 per cent of the total value.

PRODUCTION BY STATES.

The four leading States in 1918, which contributed more than 70 per cent of the total value of sandstone, were Pennsylvania ($1,543,544), Ohio ($957,535), Wisconsin ($353,030), and New York ($325,-

351). Wisconsin was the only one of these States to show increased sales—the result of a large gain in both quantity and value of ganister. All sandstone products in Pennsylvania decreased in both quantity and value except ganister, which increased in value but decreased in quantity. New York showed large decreases in all classes of sandstone and was exceeded in total value by Wisconsin. In 1913 New York ranked first among the sandstone-producing States; in 1914, second; in 1915, third; and in 1918, fourth. This decrease was due at first to the large decrease in the production of bluestone and recently to an increase in the production of ganister in other States. New York's output is mostly for construction work—building, paving, flagging, and curbing—which has necessarily been greatly curtailed in the last two years. Ohio continued in second place among the sandstone States, but with decreased value, for practically all products except ganister and flagging. The only States besides Wisconsin to show increase in value of production were Arkansas (7 per cent), for riprap; North Carolina (27 per cent), continuing the increase begun in 1917 by stone quarried for the construction of a dam; Virginia (39 per cent), for crushed stone; and West Virginia (25 per cent), for ganister. The number of quarries reporting operation in 1918 was 270, compared with 356 in 1917 and 436 in 1916.

Value of sandstone (including quartzite and bluestone) sold in the United States, 1914–1918.

State.	1914	1915	1916	1917	1918
Alabama	$161,773	$30,432	$20,995	$17,098	$14,484

PRODUCTION BY USES.

The quantity and value of sandstone sold are summarized by uses in the first of the accompanying tables and are given in more detail in the second. In the first table quantities are expressed in the units ordinarily used by the trade and also approximately in equivalent short tons.

Sandstone sold in the United States in 1917 and 1918, by uses.

Use.	1917		1918	
	Quantity.	Value.	Quantity.	Value.
Building stone.....cubic feet..	[a] 2,579,750	$1,043,226	973,990	$536,474

BUILDING STONE.

Sandstone for building purposes decreased from 2,579,750 cubic feet, valued at $1,043,226, in 1917 to 973,990 cubic feet, valued at $536,474, in 1918, a decrease of 62 per cent in quantity and of 49 per cent in value, and following a decrease of 32 per cent in quantity and 20 per cent in value in 1917. The average price was 40 cents a cubic foot ($4.93 a ton) in 1917 and 55 cents ($7.09 a ton) in 1918.

The increase in value of stone sold rough for building and the large decrease in the value of dressed stone sold is partly accounted for by a difference in classification in 1917 and in 1918. In 1917 all sawed stone was included under dressed stone, while in 1918 the rough sawed stone was included with rough blocks.

The three principal producing States were Ohio, New York, and Pennsylvania.

The chief localities in Ohio that furnished building stone were the well-known districts near Amherst and North Amherst in Lorain County; Berea and South Euclid in Cuyahoga County; Wakeman in Huron County; McDermott in Scioto County; the more recently developed districts at Glenmont in Holmes County; and Sherrodsville

in Carroll County. In New York, the bluestone quarries near Norwich in Chenango County and Portageville in Wyoming County furnished most of the building material. In Pennsylvania, besides the quarrying of building stone at Waltonville in Dauphin County, there were no special operations for building sandstone in 1918, although stone in stock was sold from a number of small quarries. The sandstone quarries in Stone City, Pueblo County, Colo., which furnished a considerable quantity of building stone in 1917, were less active in 1918. There was increased production of building stone in 1918 at the Table Rock quarries near Boise in Ada County, Idaho, which furnished stone for some new dormitories of Yale University, New Haven, Conn. Output decreased at the "freestone" quarries near Farmers and Freestone in Rowan County, Ky. The quarry at Langfords in Rockcastle County was idle during 1918, as were the quarries at Kingwood in Preston County, W. Va.; and at Port Wing in Bayfield County, Wis. The quarries at Colfax and Dunnville in Dunn County, Wis., decreased in output of building stone in 1918. The selling of the stone from the Dunnville quarries, which has long been used throughout Wisconsin, in St. Paul and other places in Minnesota, in Iowa, North Dakota, and South Dakota, as a building stone, has recently been placed in the hands of a New York firm, and stone from these quarries has been shipped to New York for interior decoration of the Richmond County courthouse at Richmond, N. Y. There was less building stone quarried at Jacobsville, Houghton County, Mich., in 1918, and it was reported that this quarry, which has furnished building stone for many years, has been abandoned. There was increased production at the building-stone quarries near Wilkeson in Pierce County, Wash., in 1918. The remainder of the building sandstone sold was from less known localities and mostly for local use.

PAVING BLOCKS.

The sandstone sold for paving blocks in 1918 amounted to 21,900 tons (2,188,419 blocks), valued at $148,091. This was a decrease of 49,049 short tons (4,905,081 blocks) in quantity and of $204,717 in value. The average price was $6.76 a ton ($67.67 a thousand blocks) in 1918 and $4.97 a ton ($49.74 a thousand blocks) in 1917. Sandstone paving blocks were reported from five States in 1918 compared with seven States in 1917 and 13 States in 1916. New York, Pennsylvania, and Wisconsin were the principal producers, with small outputs from Minnesota and Washington. The relation of producing centers to markets is illustrated on Plate XIV. In Minnesota the paving blocks are produced at Sandstone in Pine County, and in 1918 they were all shipped to St. Paul. The sandstone paving blocks sold in New York in 1918 decreased in value $87,158 (51 per cent) compared with 1917. The producing localities were near Albion and Hurlburton, Orleans County (1,072,513 blocks valued at $74,960), and at Hammond, St. Lawrence County (169,750 blocks valued at $9,448). The blocks made in these two districts were shipped to Buffalo, N. Y. (432,375 blocks), Cleveland, Ohio (390,478 blocks), Rochester, N. Y., and Akron, Ohio (each about 105,600 blocks), Oswego, N. Y. (37,860 blocks), and the remainder to Tonawanda, Syracuse, and Amsterdam, N. Y.

Sandstone paving blocks produced in Pennsylvania in 1918 decreased in value 64 per cent, compared with 1917. The blocks were produced at Whitehaven in Luzerne County and were shipped to Scranton, and at Branch, Long Bridge, Hillside, and Ligonier in Westmoreland County and were shipped to Pittsburgh. The total quantity was 418,759 blocks. The sandstone paving blocks reported from Washington were quarried at Wilkeson in Pierce County, and no statement was made of the locality of consumption, but it was probably Seattle. The sandstone paving blocks produced in Wisconsin were from Ableman in Sauk County, Stevens Point in Portage County, and Grand Rapids in Wood County. The total amounted to 334,846 blocks, valued at $24,146, a decrease of 46 per cent in value for 1918. These blocks were all shipped to Milwaukee.

CURBING AND FLAGGING.

The sandstone sold for curbing and flagstone, which in 1918 represented about 4 per cent of the total quantity and 15 per cent of the total value of all sandstone sold, has shown a continuous decrease for several years, caused by the increasing use of concrete for these purposes. The value of the curbing sold in 1918 was $298,971—$352,593 less than in 1917. The value of flagging was $373,729, an increase of 7 per cent. This increase was occasioned by increase in average price, as the quantity sold decreased about 22 per cent.

The calculation of figures of quantity for these two products is found to be rather unsatisfactory, inasmuch as many of the producers report the quantity of curbing sold in linear feet and the quantity of flagging in square feet. As there is no standard for the other dimensions necessary for conversion to a common unit, the conversion to cubic feet has been based on an average thickness for both products. Curbing varies from 2 inches to 8 inches in thickness and the length 18 inches to 2 or 3 feet or more. Flagging varies from one-half inch to 5 inches in thickness, the average being about 2½ inches. Ohio, which is the largest producing State for both curbing and flagstone, showed decrease in both quantity and value of curbing, but decreased quantity with increased value for flagging.

New York and Pennsylvania, the only other States which produce these products to any extent, showed large decreases in both quantity and value of output.

RUBBLE AND RIPRAP.

The sandstone sold for rubble, the cheapest form of stone building material, did not show as large a decrease in 1918 as might have been expected from the conditions of labor and the building trades. The output was 105,022 tons, valued at $107,958—a decrease of 28 per cent in quantity, but an increase of 64 per cent in value. The average price in 1917 was 45 cents, in 1918 it was $1.03. The sandstone sold for riprap which is subject to irregular demand for construction and repair of river and harbor work increased in both quantity (4 per cent) and value (16 per cent). The output in 1918 was 356,784 short tons, valued at $305,308.

As the production of riprap and rubble is confined usually to only one or two producers in most of the States, very few State figures can be published.

GANISTER.

Sandstone (quartzite) in its use as ganister or refractory material for making silica brick, ferrosilicon, and furnace or converter linings, took its place during the war as an important stone product. This was shown by its increase of 50 per cent in quantity in 1916 and of 51 per cent in 1917.

This great increase, when compared with the smaller increases of materials on which its use formerly depended, suggests a broadening of its usefulness supplementing or displacing certain other refractories. One cause of its increased use was the growth of the by-product coke industry in which ganister bricks have proved very satisfactory. The requisite qualities for ganister are a content of 98 per cent of silica (SiO_2) and not more than 1½ per cent of alumina and the ability to be finely crushed into fine angular fragments. Loose sand and sandstones that are reduced to the original rounded sand grains on crushing yield a weaker brick, less able to withstand either handling before burning or the changes in volume during burning, when the original quartz is transformed to a microcrystalline mass of tridymite and cristobalite. The great increase in demand for ganister has caused the opening of new quarries in the producing districts, but very few inquiries have been made by prospective producers regarding the location of undeveloped deposits.

Detailed information on the manufacture, properties, and uses of silica brick is contained in the following articles:

McDowell, J. S., A study of the silica refractories: Am. Inst. Min. Eng. Trans., vol. 57, pp. 3–61, 1918.

——— Composition of refractory silica brick: Eng. and Min. Jour., May 25, 1918, pp. 954–956.

Le Chatelier, H., and Gogitch, B., The manufacture of silica brick: Am. Inst. Min. Eng. Bull., September, 1918, pp. 1435–1462.

Gray, Walter, Silica brick and some new uses of them: Met. and Chem. Eng., Feb. 15, 1917, pp. 209–216.

Ross, D. W., Silica refractories: U. S. Bur. Standards Tech. Paper 116, 1919.

The ganister used in 1918 amounted to 1,297,874 short tons, valued at $1,688,334. The quantity produced is nearly 0.3 per cent less than that produced in 1917. This slight decrease shows a check on the rapid development of the industry. In 1918 the value increased 25 per cent; in 1917 it increased 155 per cent; and in 1916, 58 per cent. In 1918 the average price per ton was $1.30; in 1917 it was $1.04; and in 1916 it was 62 cents. The advance in price in 1918, as in 1917, was due mainly to increase in the cost of production, and the decrease in output was due to scarcity of labor and the cessation of abnormal demand after the armistice was signed, in November, 1918.

Ganister sold in the United States in 1915–1918.

Year.	Quantity (short tons).	Value.	Year.	Quantity (short tons).	Value.
1915	573,304	$336,267	1917	1,301,177	$1,350,500
1916	859,956	529,805	1918	1,297,874	1,688,334

In 1918, for the first time, the statistics of ganister were assembled to show the production of the stone according to uses, and the result is given in the following table:

Ganister sold in the United States in 1918, by uses.

State.	Silica brick.		Furnace and converter linings.		Ferrosilicon.		Total.

[a] Ferrosilicon included under furnace and converter linings.
[b] Ferrosilicon included under silica brick.
[c] Furnace and converter linings included under ferrosilicon.
[d] Includes Alabama, Illinois, Minnesota, Montana, New York, and South Dakota.

More than 77 per cent of the total quantity produced was used in the manufacture of silica brick. There were 336,562,000 silica brick manufactured in 1918, but these were not all made from ganister, as a considerable quantity of silica (sand) was also used.

In 1918, 64 plants reported operations, 36 of which were in Pennsylvania, 6 in Wisconsin, 5 in Colorado, and 3 in Ohio; and the remaining plants were in 10 other States, in none of which were there more than two companies.

Pennsylvania produced 77 per cent of the total output in 1917 and 66 per cent in 1918, Pennsylvania's production for the last three years being as follows:

Ganister sold in Pennsylvania, 1916–1918.

Year.	Quantity (short tons).	Value.	Average price per ton.
1916	675,424	$410,541	$0.61
1917	1,001,630	1,114,696	1.11
1918	858,374	1,142,202	1.33

These figures show an increase in quantity of 48 per cent in 1917 and a decrease of 14 per cent in 1918. The value, however, increased 171 per cent in 1917 and 2.5 per cent in 1918. About 80 per cent of Pennsylvania's total output in 1918 was used in the manufacture of brick, of which 233,143,000 were manufactured in 1918. About 17 per cent of the ganister went for furnace and converter linings and about 6 per cent for ferrosilicon.

Pennsylvania is the largest producer of each ganister product, 36 plants reporting operations in 1918, of which 4 were new. One plant that was working in 1917 was idle in 1918. Huntingdon County produced 417,252 short tons, valued at $517,915, of which all but a very small part, sold for furnace and converter linings, was used for silica brick. Blair County produced 262,079 short tons, valued at $364,832, of which 209,809 short tons, valued at $281,960, was used for silica brick, and the remainder, except a small quantity used for furnace and converter linings, went into ferrosilicon. Bedford County, with an output of 105,347 tons, valued at $128,654, used a small quantity for ferrosilicon and about equal quantities for silica brick and furnace and converter linings. The remainder of the output of Pennsylvania came from Carbon, Center, Fayette, Lancaster, Lawrence, Mercer, Mifflin, Montgomery, and Somerset counties.

The production of ganister in Wisconsin, where six plants were in operation, increased 24 per cent in quantity and 82 per cent in value in 1918. Practically all the output was used in making silica brick, a small portion being used for furnace and converter linings. All the material used for making silica brick was shipped out of the State as there are no manufacturers of this product in Wisconsin. The producing localities were Grand Rapids, Wood County; and Ableman, Devils Lake, and North Freedom, Sauk County.

Ohio, the third largest producer, reported sales of 48,019 tons of stone, valued at $102,447, all used for furnace and converter linings. This stone, unlike that produced in the other States reporting sales of ganister, is not quartzite but the well-known sandstone of northern Ohio, used principally as a building stone or for making grindstones. The producing localities were Berea, Cuyahoga County; Leavittsburg, Trumbull County; and Amherst and North Amherst, Lorain County. This is the first time that the total production of this stone for this use has been reported for this State.

Colorado, the only other State whose output can be reported separately, produced 43,051 short tons, valued at $56,163, in 1918. These figures show an increase of 22 per cent in quantity and 75 per cent in value over 1917. This stone all came from the vicinity of Canon City, Fremont County, and from Stone City, Pueblo County. More than half of the product is used for silica brick and most of the remainder is sold to steel plants for furnace lining, only a small portion being used in the manufacture of ferrosilicon.

The production of ganister in Illinois, South Dakota, Tennessee, and West Virginia increased in both quantity and value, and that of Alabama and New York decreased. Minnesota, for the first time, reported the sale of blocks for furnace and converter linings from the quarries at Sandstone, Pine County. The material quarried near Rock Run, Cherokee County, Ala., was used in the manufacture of fire brick. Illinois produced a cherty rock, locally called "novaculite," in Elco and Tamms, Alexander County, which was used in the manufacture of silica brick. The product of Maryland came from the vicinity of Cresaptown, Allegany County, and was used in the manufacture of ferrosilicon. The quarry at Bloomington, Garrett County, was idle in 1918. In New York ganister was quarried near Johnstown, Fulton County, and was used in the

manufacture of ferrosilicon. The product of South Dakota was quarried near Sioux Falls, Minnehaha County, and was used about equally in the manufacture of silica brick and ferrosilicon, though a quantity of cut jasper was sold for furnace and converter linings. Tennessee produced a small quantity of ganister in the neighborhood of Alton Park, Hamilton County, which was used for furnace lining. West Virginia more than tripled its production in 1918, and the value of its product was nearly six times as much as in 1917. It was quarried at Great Cacapon and Berkeley Springs, Morgan County, and was used in the manufacture of silica brick and ferrosilicon. Montana for the first time reported a production of sandstone for use as furnace or converter lining from quarries at Field, Cascade County. Quartzite, used for furnace or converter lining was quarried at Ranger and Kinsey, Cherokee County, N. C., and shipped to Tennessee.

CRUSHED STONE.

Crushed sandstone in 1918, for the fourth year in succession, decreased in sales—42 per cent in quantity and 25 per cent in value. The largest decrease was in crushed stone for concrete, which declined about 46 per cent in quantity and 25 per cent in value.

The average price increased from $0.92 in 1917 to $1.19 in 1918. About one-fourth of the quantity sold was quarried in Pennsylvania, 221,733 short tons, valued at $256,448. North Carolina, whose output was chiefly used in the construction of a dam, stood third in quantity, but second in value; Massachusetts stood fourth in quantity, but third in value; and California stood second in quantity, but fourth in value.

BLUESTONE.

The bluestone industry of eastern New York and northeastern Pennsylvania, which was at one time of considerable importance, has almost entirely ceased. The value of bluestone quarried and sold in 1918 was $221,114. In 1911 the value of the bluestone produced was $1,876,473. Bluestone was chiefly used for curbing, flagging, and for sills, lintels, and other trimming on buildings and has been replaced largely by cement. It is very doubtful that any revival of this industry will take place, unless called for by some unusual local demand. The following tables show the condition of this industry for the last eight years:

Value of bluestone sold in the United States, 1911–1918.

Year.	Value.	Year.	Value.
1911	$1,876,473	1915	$641,446
1912	1,505,763	1916	510,011
1913	1,280,862	1917	427,896
1914	1,086,699	1918	221,114

Value of bluestone sold in New York and Pennsylvania in 1917 and 1918.

State.	Building stone.	Flagging.	Curbing.	Other uses.[a]	Total value.
1917.

[b] Included under "Other uses."

MISCELLANEOUS STONE.

The separation under the heading "miscellaneous stone" of certain different kinds, which for convenience had been included in former reports with the class of stone to which they were most nearly related, was begun in 1917 and a continuance of separation in 1918 permits a comparison for the two years. In 1918 four States—Idaho, Arkansas, Virginia, and Wisconsin—were added to those producing miscellaneous stone. The kinds of stone included under this heading are light-colored volcanic rocks (Massachusetts, North Carolina, South Dakota, Colorado, Arizona, California, Oregon); conglomerate and "grit" (Massachusetts, New York, Pennsylvania, and Virginia); slate and argillite (Massachusetts, New Jersey, Pennsylvania); chert and cherty limestone or "flint rock" (Arkansas, Florida, Missouri, Oklahoma); taconite or "iron ore rock" (Michigan; mica schist (New Hampshire, Rhode Island, Pennsylvania).

LIGHT-COLORED VOLCANIC ROCKS.

The light-colored volcanic rocks include principally rhyolite, trachyte, and andesite (chiefly lava flows) and related tuffs, or consolidated volcanic ash. Other rocks that would be included in this subgroup are dacite, phonolite, and some basaltic tuffs of light color. Any one of these rocks, except the tuffs, whether in flows or dikes, may be locally termed porphyry, if it contains distinct crystals scattered through a relatively fine grained or dense groundmass. These rocks differ considerably in physical properties, according to differences in their mode of origin and subsequent alteration. Some, particularly rhyolites, which are quarried to a considerable extent for crushed stone in eastern Massachusetts, at one place in North Carolina, and in certain parts of California, are hard and of flinty character; others, quarried mainly for local use as building stone in Colorado, South Dakota, and States west of the Rocky Mountains, are comparatively soft and in some places have been called sandstones, owing to their general resemblance to sandstone when placed in buildings, and, as regards the tuffs, to their mode of occurrence. In some regions soft light volcanic tuffs, called "trass," has been quarried for such refractory uses as fireplaces, stove linings, and chimneys.

CONGLOMERATE AND "GRIT."

Conglomerate, or "puddingstone," is quarried in the vicinity of Boston, Mass., and formerly supplied a considerable local demand for building stone; but for several years it has been quarried mainly for crushed stone. Conglomerate is also quarried near Otisville, Orange County, N. Y. The Rensselaer "grit," a dark, hard sandstone, resembling diabase in appearance and physical properties, is quarried at Brainard, Rensselaer County.

SLATE AND ARGILLITE.

A massive slate with no indication of true slaty cleavage has also supplied former demands for building stone and present demands for crushed stone in the vicinity of Boston. At present it is quarried at Somerville and Watertown, Mass. Argillite, which supplies a considerable quantity of crushed stone in New Jersey and eastern Pennsylvania, is a shale hardened through the influence of intruding masses of igneous rock into a dark-gray to black stone, which rather closely resembles diabase or basalt (trap rock) in appearance and physical properties.

CHERT AND CHERTY LIMESTONE.

Cherty limestone, or flint rock, also lumps of chert or flint left by the weathering of these limestones are crushed for road metal and railroad ballast in Florida, Missouri, and Oklahoma.

TACONITE.

Taconite, or "iron ore rock," is a cherty or jaspery rock closely associated with iron ores in the Lake Superior region. In some places it is calcareous and in others quartzitic. Small quantities of this rock have been taken from the waste dumps of mines in Michigan and crushed for road metal.

SALES.

The total sales of miscellaneous stone in 1918 amounted to 844,740 short tons, valued at $973,034. This was a decrease of 2 per cent in the total value and of 32 per cent in quantity. The sales for different uses in 1918 are summarized in the first of the following tables, and sales itemized so far as possible by States are shown in the third.

Miscellaneous varieties of stone sold in the United States in 1918.

Use.	Quantity.	Value.

a Included in "Undistributed."

The value of the output of Massachusetts and Pennsylvania together, in about equal proportions, represents more than one-half of the total. The stone from Massachusetts is chiefly sold as crushed stone, whereas one-half of the Pennsylvania product is sold for miscellaneous purposes, of which mica schist for refractory use forms the greater part.

About 88 per cent of the total quantity and 74 per cent of the total value of this miscellaneous stone is represented by crushed stone. The total production of crushed stone, 743,292 short tons, valued at $738,486, represents a decrease of 25 per cent in quantity and 12 per cent in value, compared with 1917. In 1918, 49 per cent of this crushed material was used for concrete, which increased 47 per cent in quantity and 89 per cent in value, due to large increases in output in Massachusetts and Pennsylvania. The stone used for road metal and railroad ballast decreased in both quantity and value.

In Virginia and in Pennsylvania a green stone is crushed into granules and used as a coating for an asphaltic felt which has been in considerable demand as a roofing material. Red and green slate granules quarried in New York and Vermont were also used in large quantities for this purpose. It is also stated that green trap rock granules from the quarries at Marquette, Mich., will be utilized for this purpose.

MICA SCHIST AS A REFRACTORY.

Sales of mica schist or "fire stone" for refractory use, mainly in the steel industry, amounted in 1918 to 36,446 short tons, a decrease of nearly 9 per cent. Its value, however, owing to increased costs of operation, was $114,611, an increase of more than 33 per cent. Sales for the last three years are as follows:

Mica schist sold for refractory uses, 1916–1918.

Year.	Quantity (short tons).	Value.
1916	33,236	$47,304
1917	39,975	85,986
1918	36,446	114,611
Percentage of change in 1918	−8.8	+33.3

This stone is quarried at Edge Hill, Ardsley, and Glenside, Pa., from steeply dipping beds of thinly foliated quartzose mica schist. A sample submitted by the Edge Hill Silica Rock Co. is yellowish white, irregularly clouded with black, and consists mainly of quartz and white mica (muscovite). The yellowish tinge is due to films of iron oxide (limonite) accompanied by a little kaolin along the foliation planes and has evidently resulted from the weathering of muscovite. The black clouding is due to small grains of ilmenite and perhaps to a little black mica and tourmaline. Partial chemical analyses show about 90 per cent of silica.

In thin sections, cut perpendicular to the foliation, quartz forms typical mosaics of interlocking elongate grains up to 1 millimeter in length. The largest mosaics are from 2 to 3 millimeters long.

Muscovite forms typical aggregates of flakes, few groups exceeding 1 millimeter in length. Small isolated grains lie between or within quartz grains. The longer aggregates tend to fork and partly inclose quartz mosaics. Nearly all the larger muscovite aggregates are slightly stained by yellow to brown iron oxide, the iron perhaps coming from minute pyrite grains now represented by clusters of black specks. No distinct kaolinization was found, and the kaolinized flakes were apparently lost during the grinding of the section. The ilmenite forms irregular grains from 0.5 millimeter in diameter down to mere specks, some of them considerably altered to leucoxene. Titanite forms small rounded grains, some inclosed by ilmenite, others well removed from it. No tourmaline or biotite was found.

The stone, according to the producers, is used principally for lining Bessemer converters (standard and side-blow), acid open-hearth furnaces, reverbatory furnaces, air furnaces, foundry cupolas, ladles, mixers, and soaking pits, and is suited for any other furnace or vessel calling for acid lining. It is said to have lasted in Bessemer converters, in which the temperature rises to 3,500° F. (1,925° C.), for 18 months, although, as shown later, it is doubtful if more than the very surface of the stone was subjected to quite so high a temperature. It is also said to be suitable for lime and cement kilns, day and continuous tanks and pot furnaces in glass manufacture.

A sample of mica schist removed from a furnace lining after 18 months of use was also submitted by the Edge Hill Silica Rock Co. It shows at the surface a vesicular black glass or slag that has penetrated and replaced the stone for a distance of one-quarter of an inch to 1 inch. This grades into a rather porous gray zone of somewhat glassy luster and this is followed by purplish, reddish, and light-red zones, each zone about an inch thick. The mica in the light red and red zones has lost its bright silvery luster and turned to a light brown color. It is not visible in the other three zones.

Thin sections were cut from each of the five zones. That from the light-reddish zone, 5 inches from the slaggy surface, showed the quartz to be unchanged unless reduced to slightly finer grains. The muscovite was all converted to yellowish-brown to reddish material, largely amorphous and nearly opaque, but in part very finely fibrous and weakly birefringent. The color was evidently due to iron oxide which had deposited by emanations from the furnace working along the layers of dehydrated muscovite. The schistosity was preserved almost if not quite perfectly, although the altered muscovite layers appeared a little more prominent. In the section 4 inches from the surface the quartz showed no further change. The mica layers were redder and more completely isotropic. Iron was evidently present in somewhat greater quantity, but scattered bubblelike cavities in these layers suggested that a little fusion and partial volatilization of the iron-muscovite material had begun. The fusion of iron-free muscovite alone would indicate a temperature of 1200°–1300° C.,[34] but the presence of the iron, which acts as a flux, lowers the temperature of fusion appreciably. Three inches from the surface, in the purplish

[34] Doelter, C., Handbuch der Mineralchemie, Band II, 8, p. 437, 1915.

zone, the quartz continued unchanged, but the iron oxide had partly disappeared, leaving a white opaque material. The presence of several cavities suggested partial removal of this white material by vaporization, leaving cavities bordered by rims of dark glass. The dark color of the glass was due to minute inclusions, some of them bubbles and some opaque, and relatively large scales of red iron oxide. The yellowish-gray zone, 2 inches from the surface, showed the quartz to have been appreciably replaced by glass, which encroached from the original muscovite layers and penetrated along the boundaries between the grains. Quartz alone would melt or invert to cristobalite at a temperature somewhat below 1470° C.[35], but here again the fluxing action of the glass doubtless lowered the temperature. The glassy material contained minute indeterminate inclusions as before, and also minute rod-shaped crystals, presumably sillimanite. Within an inch of the surface, the quartz was still further replaced by brownish glass or cristobalite. Any cristobalite, however, was so finely divided as to be apparently isotropic. Many grains had cracked and the cracks had been filled with the apparently isotropic material. About one-fifth of an inch (5 millimeters) from the surface a little colorless isotropic material appears replacing the quartz and in turn replaced by the brownish isotropic material. The quantity of colorless isotropic material increases toward the heated surface but had not entirely replaced the quartz, until about one-twelfth of an inch (2 millimeters) from the surface, where almost no remnants of quartz or of schistose structure remained. The glass within an inch of the surface is crowded with minute opaque specks and contains many minute groups of platy crystals, evidently cristobalite or tridymite, but still without appreciable birefringence; also more distinct though very small crystals of sillimanite, which become rapidly more abundant until within 2 millimeters of the surface they attain lengths of nearly 0.5 millimeter and the glass is thickly spangled with them. Traces of unchanged ilmenite and titanite were found 3 inches from the surface, and one titanite partly fused along fractures was found 2 inches from the surface.

The temperatures indicated by most of these changes are indefinite because of the fluxing action of minor constituents of the mica schist and of the molten iron and impurities in the furnace charge. Temperatures at which some of these changes would take place without fluxes are known, however, and may serve as an approximate indication. The change from quartz to the colorless material (cristobalite or silica glass) evidently took place without the aid of the flux, which would have produced a colored glass, and therefore would indicate a temperature somewhat below 1470° C. attained within 5 millimeters of the surface; but as this change progresses slowly in quartz that has not been finely ground, the temperature actually reached may have been somewhat higher. The eutectic mixture of the binary system silica-alumina contains about 90 per cent of silica and 10 per cent of alumina, a ratio approximated by these constituents in the mica schist. The melting point of this eutectic without fluxes is slightly

[35] Fenner, C. N., The stability relations of the silica minerals: Am. Jour. Sci., 4th ser., vol. 36, pp. 338, 383, 1913.

below 1600° C.,[36] and with the fluxes present would be lowered to an unknown extent. The fact that the block of mica schist in question had been in use for 18 months implies that the highest temperatures to which it was subjected could not have exceeded these indicated temperatures very much.

CRUSHED STONE.

GENERAL STATISTICS.

Crushed stone which represented 43 per cent of all stone sold in 1918 decreased in production 27 per cent (10,912,035 short tons). This followed a decrease of 16 per cent in 1917, and of 2 per cent in 1916. The total sales in 1918 amounted to 29,373,342 short tons, of which 65 per cent represented limestone, 22 per cent basalt and related rocks (trap rock), 7 per cent granite, and 6 per cent nearly equally divided between sandstone and miscellaneous varieties of rocks. The value of the crushed stone sold was $27,951,393, a decrease of nearly 4 per cent ($1,114,116). This is the lowest value recorded for crushed stone since 1910, and the quantity represents the smallest output since 1906. The average price was 95 cents in 1918, an increase of 23 cents over 1917 and of 34 cents over 1916. The change in total average per short ton of crushed stone since 1905 is seen in the following table:

Average price per short ton of crushed stone, 1905–1918.

Year.	Road metal.	Railroad ballast.	Concrete.	Total crushed stone.
1905	$0.64	$0.48	$0.67	$0.59
1906	.64	.49	.65	.59
1907	.66	.52	.71	.63
1908	.62	.52	.65	.61
1909	.67	.48	.64	.61
1910	.62	.48	.64	.59
1911	.62	.50	.65	.59
1912	.60	.49	.67	.59
1913	.63	.51	.67	.61
1914	.61	.51	.68	.61
1915	.60	.50	.65	.60
1916	.63	.49	.67	.61
1917	.75	.56	.78	.72
1918	.97	.77	1.05	.95

There has been no increase or decrease of more than 2 cents a ton in total average price except in the year 1907 (increase of 4 cents) until 1917, when increased cost of supplies and labor caused an increase of 11 cents. The average price of the different uses of stone showed a somewhat wider range of difference, but with no decided change until 1917.

Crushed stone is used principally for road metal, railroad ballast, and concrete. The concrete is used in building and construction work, for curbing and flagging, for stucco, and has found increased use in the last few years in the building of roads. The largest decrease in quantity in 1918 was stone used for road metal (36 per cent)

[36] Shepherd, E. S., and Rankin, G. S., The binary systems of alumina with silica, lime, and magnesia: Am. Jour. Sci., 4th ser., vol. 28, p. 301, 1909.

and the smallest in railroad ballast (15.5 per cent). Concrete decreased 25 per cent. Railroad ballast was the only use for which any considerable increase in value was given (16 per cent) but neither this increase nor the small increase (1 per cent) in the value of concrete, was enough to offset in the total value the decrease of nearly 18 per cent in the value of road metal. The only crushed-stone products which showed increase in quantity were basalt and related rocks (trap rock) used for railroad ballast, which increased less than 1 per cent, and miscellaneous stone for concrete, which increased 46 per cent.

Crushed granite, the sales of which in 1918 amounted to 2,069,473 short tons, valued at $2,583,449, decreased 32 per cent in quantity and 4 per cent in value. Basalt, the sales of which as crushed stone, amounted to 6,556,888 short tons, valued at $7,306,168, decreased 19 per cent in quantity but increased about 11 per cent in value. Sandstone, of which 882,831 short tons, valued at $1,050,106, was sold, decreased 42 per cent in quantity and 25 per cent in value. Limestone, of which 19,120,858 short tons, valued at $16,273,184, was sold, decreased 28 per cent (7,525,784 short tons) in quantity but only 7 per cent ($1,267,914) in value. The quantity of miscellaneous varieties of stone sold as crushed stone was 743,292 short tons, valued at $738,486, a decrease of 25 per cent in quantity and 12 per cent in value.

PRODUCTION BY STATES.

Crushed stone was produced in 47 States in 1918, as in 1917, although Idaho appeared among the crushed stone States and Nevada dropped out of the list. Of the States whose production is shown separately in the accompanying tables, only three, Georgia, South Carolina, and Tennessee, showed increase in both quantity and value. Tennessee's increase was in road metal and concrete, and Georgia's and South Carolina's in concrete. It is noteworthy that the only three increases in quantity should be in States in the same section of the country. Of the remaining States, 23 decreased in both quantity and value and 11 showed increased value. In 1911, 8 States produced more than 1,000,000 short tons each of crushed stone, compared with 14 in 1917.

Ohio, New York, and Illinois, with outputs of 3,987,249, 2,841,200, and 2,802,090 short tons, respectively, were the largest producers, representing, as in 1917, a little over 32 per cent of the total. In 1917 Illinois produced 4,528,572 short tons, New York 4,293,831 short tons, and Ohio 4,156,321 short tons. Ohio regained first place lost in 1917 and Illinois dropped to third. The decrease in Illinois of 1,726,482 short tons (38 per cent) was nearly 73 per cent for concrete and 23 per cent for road metal. New York's decrease was 1,452,631 short tons (34 per cent), of which 41 per cent was for road metal, 55 per cent for concrete, and 4 per cent for railroad ballast. The decrease in Ohio was only 169,072 short tons (4 per cent), which represented a decrease of 227,909 tons for road metal and 19,130 tons for concrete and a gain of 77,967 tons for railroad ballast. Illinois showed decrease in total value and Ohio and New York showed

increase. Other States showing decreases of over 400,000 tons in output of crushed stone were California, Connecticut, Indiana, Kentucky, Missouri, New Jersey, Pennsylvania, and Virginia.

Practically all road construction was discontinued in 1917 and 1918 except that necessary for repairing roads worn out by unusually heavy traffic, and the building of roads required for the transportation of war essentials. This applied to roads in the neighborhood of Army and Navy cantonments, newly established manufacturing and construction plants, and large cities which were either railroad or water transportation centers. In the meantime many of the roads in the interior or off the main line of transportation suffered either for necessary repairs or construction was discontinued for lack of labor and necessary appropriations to carry on the work. After the signing of the armistice plans were immediately made for resumption of road building and repairing, and a program inaugurated for the opening of the country by new highways, especially in the West and Northwest, which if carried out will start in 1919 the beginning of road construction that will require increased output of road material for several years, and probably continue indefinitely. A special rate was given by the Railroad Administration on crushed stone shipped for municipal work. The production of stone for concrete should also increase with the demand for road material, as concrete-road construction is becoming more and more used by road contractors. The smaller decrease in percentage of crushed stone used for railroad ballast than for either concrete or road metal is easily explained by the necessity of keeping road beds in condition to carry the enormously increased traffic, especially that coming to eastern seaports for shipment abroad, as indicated by the increased production of basalt and related rocks in Massachusetts, New Jersey, New York, and Pennsylvania.

A considerable quantity of sand, gravel, "chats" or tailings from the zinc mines in Missouri and Kansas, chert, slag, and waste from iron mines is used for road metal, railroad ballast, and concrete, roofing gravel, and other purposes supplied by ordinary crushed stone. The quantity and value of this material is not included in the figures given in this report.

According to H. A. Buehler, State geologist of Missouri, the quantity of "chats" shipped from zinc mines in 1918 amounted to 902,129 short tons, a decrease of 524,587 short tons (37 per cent), and followed a decrease of 1,464,254 short tons (50 per cent) in 1916. Nearly 70 per cent of this material was taken by the railroads of southeastern and southwestern Missouri, and the remainder was sold commercially. It is believed that most of the material was used for railroad ballast. The gravel sold in 1918 for the same uses as crushed stone amounted to 20,640,101 short tons, valued at $11,791,073, a decrease of 18 per cent in quantity but a slight increase in total value. Railroads also reported the production for their own use of 8,064,505 short tons of sand and gravel, valued at $1,772,237, a decrease of 27 per cent in quantity but an increase in value. Further details of the crushed-stone industry are shown in the following tables, and in figures 115, 116, and 117.

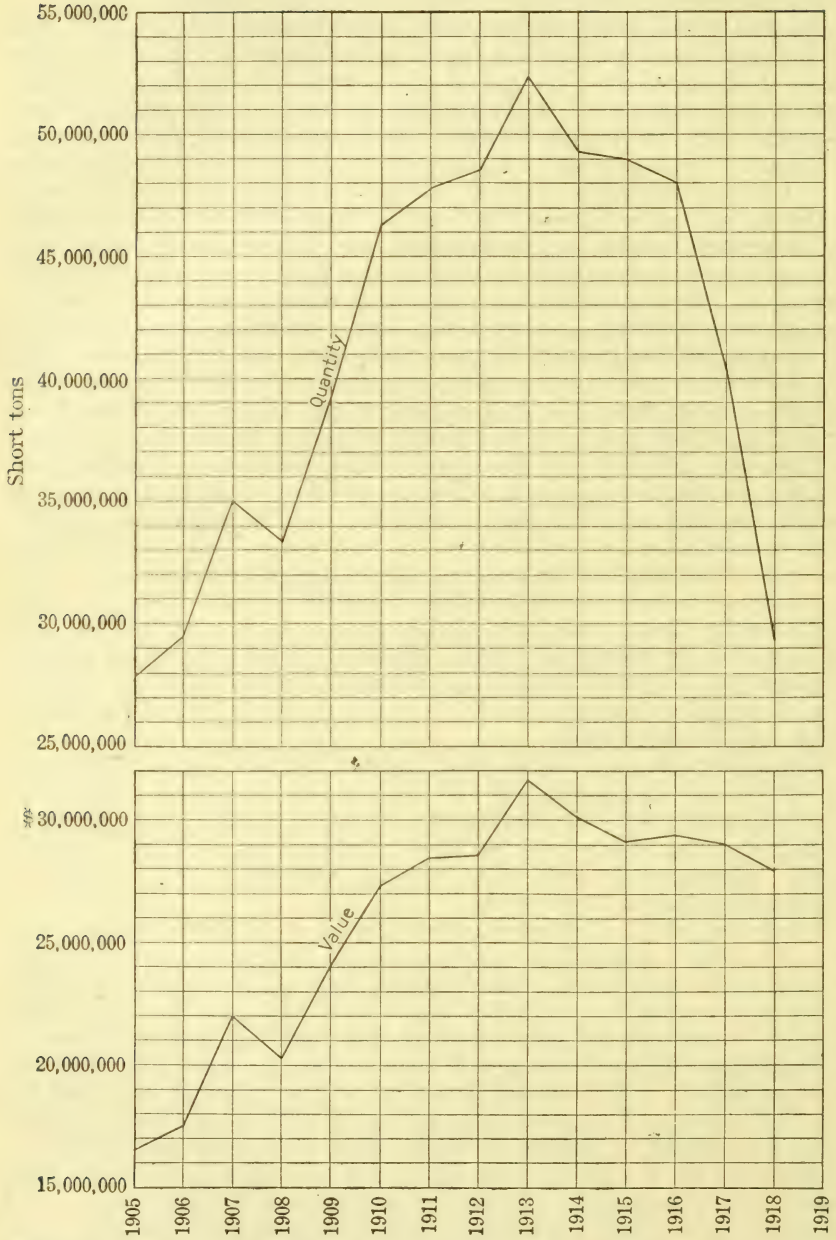

FIGURE 115.—Total quantity and value of crushed stone sold, 1905–1918. For total value in 1898–1904, see Pls. X and XII.

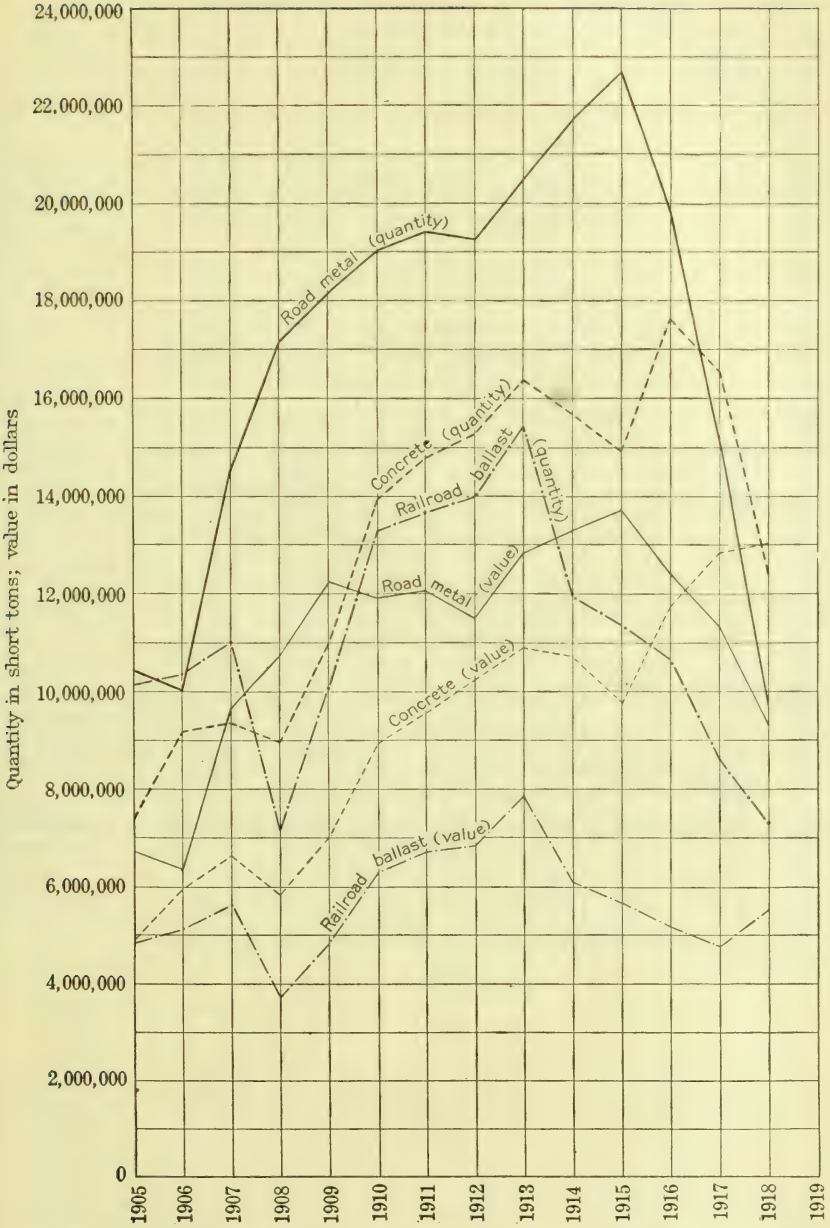

FIGURE 116.—Quantity and value of crushed stone for different uses, 1905–1918.

COAL—PART B, DISTRIBUTION AND CONSUMPTION.

By C. E. LESHER.

INTRODUCTION.

SOURCE OF INFORMATION.

The intensive study of the distribution and consumption of coal in 1918 by the Fuel Administration has made available a wealth of data on these important subjects, and the statistics presented in this report are largely drawn from the records of the Bureau of Statistics of the Fuel Administration, for the work of which the writer was responsible. The data collected in 1918 were in very great detail but did not represent a 12-month period. The field offices of the Fuel Administration were not completely organized until April, 1918, and much of the information used in the report of the bureau cited dates from that time. It has been necessary to recompile much of the material and reduce it to an annual basis and to collect some additional figures in order to obtain statistics comparable in form and scope to those presented in the corresponding chapter of Mineral Resources for 1917.

Complete and absolutely accurate reports of distribution are impossible to obtain, and any attempt to compile such statistics as are given in this report must include estimates, but it is believed that the data for 1918 are more nearly accurate than those given in the reports for 1915 and 1917, and that they are thoroughly reliable in all important aspects. The reader is referred to the report of the Distribution Division of the Fuel Administration, Parts I and III, for greater detail than is found in this summary.

UNIT OF MEASUREMENT.

The net ton of 2,000 pounds has been used as the unit of measurement throughout this report.

ACKNOWLEDGMENTS.

The writer is deeply indebted to Mr. Wayne P. Ellis, formerly assistant director of the Bureau of Statistics of the Fuel Administration, for the major portion of the statistical compilations in this report.

DISTRIBUTION OF BITUMINOUS COAL AND LIGNITE.

GENERAL FEATURES.

The statistics collected from the operators of coal mines and published in Part A of this report show the quantities of bituminous coal and lignite (1) used at the mines for generating steam and heat, (2) sold locally or used by employees, (3) used at the mines for making coke (none of this coal is shipped), and (4) shipped to market, either by rail or by river. The destination and use of the coal embraced in the first three items are thus recorded, but a special investigation was necessary to determine the destination and use of the coal shipped, which forms 86 per cent of the quantity produced.

Coal reaches the market by three general methods of transportation—(1) all rail, with which in this report are included the shipments by rivers; (2) rail to tidewater, thence by vessel to foreign markets (exports), or by vessel to other points on the coasts of the United States or its insular possessions (coastwise), or used at tidewater points for fuel on steamships (bunker); (3) rail to the Great Lakes, notably to lower Lake ports on Lake Erie, thence by boat to upper Lake ports on Lake Superior or Lake Michigan or to Canada, and from upper Lake ports again by rail to markets in the interior.

The statistics in this report show the coal consumed in each State for domestic and industrial purposes, by public utilities, both gas and electric, and by manufacturers of coke. Coal used by railroads is not shown by States but by classes of roads and by the three large recognized districts in the country.

The all-rail movement, which, as has been explained, includes shipments by rivers, is separated into (1) shipments to points within the State in which the coal was mined, with which, for convenience, are included quantities not shipped, used at the mines for steam and heat and used locally and by employees at the coal mines; (2) shipments to other States; (3) quantities used by railroads serving the coal fields or delivered by them to other railroads; and (4) exports to Canada and Mexico by rail. The details of the shipments to other States and of the tidewater and Lake movements are given in succeeding tables.

DISTRIBUTION BY ALL-RAIL ROUTES.

About 96 per cent of the bituminous coal produced in the United States is used in this country, and more than 86 per cent of the total output reaches the consumers by all-rail delivery. The States in which the coal is mined are the largest consumers, having used 36 per cent of the total output in 1918. The railroads received by all-rail delivery 149,408,000 tons, or 25 per cent of the total, in addition to which the roads in New England and the roads in the Northwest received about 9,000,000 tons by way of tidewater and Lake and from Canada. Shipments to tidewater represented 7 per cent of the total, and shipments to the Lakes 5 per cent of the total.

Distribution of bituminous coal produced in the United States in 1918, by routes and destinations.

[g] Southern Ohio includes West Virginia.
[h] Montana and northern Wyoming includes Wyoming.

DISTRIBUTION OF TIDEWATER SHIPMENTS.

The quantity of bituminous coal shipped to tidewater and dumped over piers into boats either as bunker coal or as cargo in 1918 was 44,537,684 net tons. Of this total more than 95 per cent was handled at four northern Atlantic ports—Hampton Roads, Baltimore, Philadelphia, and New York.

Foreign exports by ocean vessels (offshore) from both Atlantic and Pacific ports amounted to 4,022,000 net tons, or 9 per cent of the total tidewater dumping. Coastwise shipments, mainly to New England, amounted to 27,995,000 net tons, or about 63 per cent of the total; bunker coal for vessels engaged in both foreign and domestic trade, including bunker coal taken by Navy and Army Transport Service, amounted to 12,000,000 net tons, or about 28 per cent of the total.

Distribution of tidewater shipments of coal in 1917 and 1918.

	Quantity (net tons).		Percentage of increase or decrease, 1918.
	1917	1918	
Foreign export	5,603,782	4,022,001	−39.33
Foreign bunker	6,731,539	5,420,671	−24.18
Domestic bunker	3,597,899	[a] 7,099,956	+97.33
Coastwise, inside the Capes and New York	22,607,625	27,995,056	+23.83
	38,540,845	44,537,684	+15.56

[a] Includes Navy and Army transport bunkers.

The coal fields in central Pennsylvania were in 1918 the largest shippers of bituminous coal to tidewater, mainly to New York Harbor, for use in and about New York City and for bunker coal. The New River field was the second largest shipper of coal to tidewater, reaching Hampton Roads with coal for New England and for foreign cargo and for bunker fuel. The Pocahontas and Somerset and Cumberland-Piedmont fields followed in importance, and only three other fields—Fairmont, W. Va., Greensburg-Westmoreland, Pa., and the Kanawha district of southern West Virginia—recorded more than a million tons to tidewater during the year.

More than one-fourth of the total bituminous coal dumped at tidewater was used for steamship bunker fuel and by the Navy and Army Transport Service. Exports to foreign countries represented less than 10 per cent of the total. Shipments by vessel to New England took one-third of the total, and local use in and about New York Harbor, at Philadelphia and Wilmington, and in Chesapeake Bay accounted for 11,000,000 tons, or 25 per cent of the total.

Origin and distribution by use and destination of bituminous coal shipped to tidewater in 1918.

LAKE COAL TRAFFIC.

All records of Lake coal traffic were broken in 1918 with the loading of more than 28,000,000 net tons at lower Lake Erie ports. The requirements of both Canada and the portion of the United States dependent for its supply of bituminous coal on shipments by way of the Lakes were placed by the Fuel Administration early in the shipping season of 1918 at 28,000,000 tons of cargo coal, compared with 26,828,756 tons in 1917 and 26,830,347 tons in 1913, the previous high record. For the record of the measures that were necessary to forward that quantity of coal and the unusual and exceptional steps taken by the Fuel Administration to maintain a flow of coal from the eastern coal fields to Lake Erie, the reader is referred to the report of the Distribution Division of the Fuel Administration, particularly to the section on Lake coal in Part I and the report on the zone system in Part II.

The Lake coal program in 1917 was a subject of much debate and of several untried expedients. The Committee on Coal Production in June, 1917, brought together the representatives of the railroads and the Lake coal shippers, and as a result a pooling arrangement was effected for the purpose of reducing the detention of loaded coal cars at the lower Lake ports and thereby increasing the volume of traffic. Subsequently the Director of Transportation Priority issued an order making it mandatory for shippers of bituminous coal on all railroads tributary to the Lake Erie ports to give preference to shipments for the Lake trade. Through the operation of these measures the exceptional quantity of over 26,000,000 tons of bituminous coal was dumped at Lake Erie ports in 1917.

The pooling arrangements were made a part of the machinery of the Fuel and Railroad administrations and the boat operators in the season of 1918, but no attempt was made to reinvoke the system of priority of transportation in force in 1917. As explained in the reports of the Distribution Division of the Fuel Administration, the flow of coal to Lake Erie ports in 1918 was maintained by the control of distribution effected by the zone and budget systems. The benefits derived from the "pooling" of coal are made evident in the figures of car detention in the Lake trade. In 1916, with no regulation nor pooling and with only the demurrage rules of the railroads tending to hasten the unloading of cars of coal, the average detention or delay in unloading was 3.50 days. In 1917, with the first attempt

MAP SHOWING ORIGIN AND DESTINATION OF BITUMINOUS COAL SHIPPED ON THE GREAT LAKES AND THE ALL-RAIL MOVEMENT OF BITUMINOUS COAL TO THE NORTHWEST FROM FIELDS IN ILLINOIS AND INDIANA IN 1918

Each line represents approximately 1,000,000 net tons. Ruled areas are producing coal fields

at pooling begun in June, after the season was well under way, the average detention was 2.31 days. In 1918, with full control of both coal and the railroads, the average detention was reduced to 1.59 days. The main consideration that prompted the pooling arrangements was the saving in transportation effected by the decrease in car detention. Under normal conditions the shippers of coal do not favor pooling, because the practice eliminates to a large extent the individual "brands" of coal and prevents the vendor from realizing on that most important element in coal merchandising, the delivery of special-quality products. This is indicated by the fact that in 1916 there were 536 classifications under which coal was consigned to the lower Lake ports for transshipment. In 1917, under the first pooling arrangement, the number was reduced to 170, and in 1918 to 160. In 1919, with no public pooling and with conditions similar to those in 1916, except that the handling of Lake coal traffic was under the unified control of the United States Railroad Administration, the number of classifications was 265.

In practice the pooling arrangement operated about as follows: All shipments of coal of a certain grade, such as lump, originating on a railroad in a single field were classified as belonging to one pool, to which a number was assigned. The way bills or other documents that accompanied a car of this coal bore a record of the pool number. To make up a cargo of a given pool number any or all cars of coal of that pool were dumped indiscriminately. Under normal conditions each shipper would have held the cars of his coal at the port until a sufficient number had been accumulated to make a cargo of his special coal and would accordingly have delivered coal of a definite, known quality.

Coal even from the same bed and from near-by mines may vary considerably in quality, often for no other reason than difference in preparation. The inevitable result of pooling is to mix good and poor coals, to the disadvantage of both the shipper of good coal and the purchaser.

It will perhaps assist in the understanding of the following statistics of Lake coal traffic, to describe briefly the reasons why this traffic is maintained and why it is so large; it has not been less than 20,000,000 tons a year in the last nine years.

What is commonly known as the Northwest—Wisconsin, Minnesota, North Dakota, South Dakota, and the northern edge of Iowa, in the United States, and a portion of Canada bordering on the Great Lakes—a territory that requires coal for railroads, homes, iron and copper mines, paper mills, and growing manufacturing industries, has no local source of fuel supply. As shown on the accompanying map, the nearest coal fields to this territory are in the Appalachian region on the east and southeast—the coal fields extending from Ohio and western Pennsylvania southward to Tennessee—and those in Illinois, Indiana, and western Kentucky and in Iowa and the Southwestern States on the south. The nearest Canadian coal fields are in the Maritime Provinces on the east and in Alberta and British Columbia on the west. The Canadian market on and adjacent to the upper Great Lakes, in which the railroads are the largest consumers, is almost entirely dependent for its supply of coal, both anthracite and bituminous, on that shipped from the United States across the Lakes or by rail through the gateways at Buffalo and

Detroit. The American Northwest obtains coal by rail from the fields in Illinois, Indiana, and western Kentucky, which may be referred to as the Eastern Interior field, and by Lake from the fields in the East.

There are several reasons that explain the relatively greater increase in the use of eastern coal transported by way of the Lakes, compared with that of Eastern Interior coal, in this American Northwest market. The rail-Lake-rail movement is an economical use of transportation facilities. Each year the tonnage of iron ore produced in the Northwest for shipment to iron furnaces in the East is greater than that of coal used in the Northwest. In addition large quantities of grain are gathered in from the agricultural States about the head of the Lakes for transshipment east. The great volume of traffic on the Lakes goes east, and in normal times the operators of Lake vessels have found it profitable to take return cargoes of coal on the westbound trips at very low rates.

At the present time (1919) the approximate number of bulk freight vessels on the Great Lakes is 400, and the number used in the coal-carrying trade is about 200. It requires about 80 hours (3.3 days) for a coal-laden vessel to go from the lower Lake ports to Duluth. The coal capacity of the largest vessel in the Lake trade is 16,000 net tons. The largest cargo loaded of which there is record was 15,533 net tons on the *D. G. Kerr*, on September 5, 1919. The *Schoonmaker* has a somewhat greater cubical capacity than the *Kerr* and could load 16,000 tons of the same kind of coal, and the draft of the vessel would permit carrying that tonnage on the Lakes.[1]

Furthermore, the eastern coal is superior in quality to that produced in the Eastern Interior fields and has commanded a higher price because of its better quality. Not the least important of the reasons for the growth of the Lake trade is the desirability of the region it serves as a summer market for producers in the eastern fields, particularly western Pennsylvania, Ohio, and southern West Virginia. Under normal conditions the demand for coal is greatest in the winter and least in the summer. The Lakes are closed to navigation because of weather conditions from some time in December until the following April, and all the coal that is to be shipped by that route must be moved between April 1 and the middle of December. In that period the markets for coal reached by all rail from the eastern fields are least active, and the opportunity to maintain the operation of the mines during the summer by shipping to the Lakes is welcomed by the producer. So well recognized is this fact that the larger producers in the eastern fields tributary to the Lakes maintain organizations at the head of the Lakes and have their own docks and other equipment there, and during periods when the market near at hand is dull these producers ship coal to themselves at the head of the Lakes, where, if there is no demand during the summer, the coal is stored on the docks awaiting the winter market. The producer is thus enabled to operate his mines more or less continuously.

[1] The writer is indebted for this and other information on Lake coal traffic to Mr. Herman M. Griggs, manager, Ore and Coal Exchange, Cleveland, Ohio.

According to Mr. W. H. Groverman,[1] secretary of the Northwestern Coal Dock Operators' Association, the docks at Duluth-Superior have a combined capacity of 9,045,000 tons of bituminous coal and 1,377,000 tons of anthracite. On these docks anthracite is stored under cover. The largest single dock has a capacity of 800,000 tons of bituminous coal and 200,000 tons of anthracite, a total of 1,000,000 net tons.

The statistics of Lake coal traffic in 1918 are given in the following tables. The record of shipments to the Lake ports from Erie, Pa., on the east, to Toledo, Ohio, on the west, shows that the Pittsburgh (Pa.) field is the largest single source of lake coal, and that Toledo is the port that handles the greatest quantity. Beginning with 862,158 tons in April, the shipments, by months, increased to 5,167,646 tons in October, by far the highest ever recorded in a single month.

Coal for bunkering the Lake steamers, known to the trade as "vessel fuel," amounted to 1,615,623 net tons in 1918. Its source, by fields, is given in the following table:

Lake fuel coal, by districts, 1918.

	Net tons.
Pittsburgh	884,216
Central Pennsylvania	231
Northern Pennsylvania	5,714
Fairmont	13,665
Kanawha and Kenova-Thacker	122,115
Northern Ohio	416,080
Southern Ohio	154,611
Northeastern Kentucky	18,991
	1,615,623

Car ferries are used on Lake Erie, Lake Michigan, and Lake Ontario for carrying coal without transshipment on vessels. From the port of Charlotte, N. Y., on Lake Ontario, coal is shipped to Canada and to American points down the lake, both in cargo vessels and in car ferries. This traffic is not included in these statistics.

The car ferries on Lake Erie are used for transporting coal to Canada, but the coal so shipped is not included in these statistics because it is not moved as cargo in vessels.

The car ferries across Lake Michigan carried 257,685 net tons in 1918, originating in the districts indicated in the following table:

Bituminous coal shipments across Lake Michigan by car ferry, 1918, in net tons.

BITUMINOUS COAL AND LIGNITE SHIPPED BY RAILROADS AND RIVERS.

According to the reports furnished to the Geological Survey by the coal operators, bituminous coal and lignite shipped by railroads in 1918 amounted to 503,088,528 net tons, compared with 469,850,975 tons in 1917. The shipments, which are summarized by railroads in the accompanying table, include all coal loaded on cars at the mines. A small part of the coal shipped is carried only a short distance, perhaps only switched from the tipple to coke ovens or to some adjacent industrial plant, but the greater part is moved a considerable distance from the mines. As these statistics include fuel coal taken by railroads that serve the coal mines, not all the shipments furnished revenue to the railroads, coal for "company use" being nonrevenue freight. The statistics of coal traffic published by a railroad company usually show only revenue freight and include coal received from connecting lines as well as that originating at mines on the line. For that reason the figures given in the following table will be at variance with those that may be compiled by the railroads.

The quantities of bituminous coal and lignite shipped on each road are given in so far as they can be published without disclosing the output of individual mines. The name of every railroad on which coal was reported to have originated is given, and for most of the roads the quantity from each State. Roads on which the mines are operated by less than three companies are grouped in such a manner as to avoid disclosing the operations of mines or companies.

Shipments originating on rivers are given at the end of the table.

DISTRIBUTION OF COAL, BY PRODUCING DISTRICTS.

CENTRAL PENNSYLVANIA.

The distribution of coal from central Pennsylvania in 1918 was influenced by the Fuel Administration program, which required increased shipments from this field to New England. During the year New England received by rail from central Pennsylvania nearly 1,000,000 tons of coal more than in 1917. The quantity used within the State of Pennsylvania declined in part because of the decrease in the use of coke in beehive ovens in the central Pennsylvania field. The shipments to tidewater increased, and the shipments by rail and Lake Ontario to Canada increased from 4,140,000 to 4,344,000 tons. The quantity of railroad fuel shipped by all-rail routes was about the same in both years.

Distribution of coal produced in central Pennsylvania [a] in 1917–18.

[b] Includes 229,351 tons of railroad fuel by way of Lake Ontario.
[c] Does not include railroad fuel shipped by tidewater and by Lake Ontario.
[d] Exports to Canada by way of Lake Ontario in 1918 included in rail exports.

NORTHERN PENNSYLVANIA.

The coal from the district here described as northern Pennsylvania is shipped largely to consumers in Pennsylvania and New York and used as railroad fuel. Next in importance as consumers of coal from this district are Canada, New England, New Jersey, and Ohio.

Distribution of coal produced in northern Pennsylvania [a] in 1917–18.

[a] Includes the western part of Armstrong; Beaver, Butler, western part of Clarion, northwest corner of Indiana; Lawrence, and Mercer counties, Pa.
[b] Does not include 15,000 tons of railroad fuel shipped by Lake.

WESTMORELAND, GREENSBURG, LATROBE, AND LIGONIER DISTRICTS, PA.

The coal from the Westmoreland, Greenburg, Latrobe, and Ligonier districts is largely (34.8 per cent) taken by the railroads for fuel, the Greensburg and Ligonier districts being predominantly sources of locomotive fuel and the Westmoreland district the source of high-grade gas coal for passenger-engine service on the Pennsylvania Railroad. Little of the coal from these districts is used for other than railroad fuel and industrial purposes, including by-product coke manufacture and steel mills. The Westmoreland coal, that from the Irwin basin, is noted for its high quality for making gas and is used, largely in New England, for this purpose in establishments that furnish gas to municipalities. In the Latrobe district particularly this coal is coked in beehive ovens. Including the coal coked in beehive ovens, about 40.8 per cent of the product of these districts was used in Pennsylvania. The zoning system had little effect on the distribution of this coal in 1918. The efforts of the Fuel Administration in these districts were directed more largely toward obtaining a better utilization of the higher-grade coals, especially that from the Westmoreland district, the production of which was not increased as much as in the other parts of the field. The increase in total production of about 800,000 tons was more than offset by the increase in railroad fuel, and as a consequence decreased shipments were sent to consumers in Pennsylvania, New England, Ohio, and New Jersey, but larger shipments went to New York, and a slightly greater quantity to tidewater.

Distribution of coal produced in Westmoreland, Greensburg, Latrobe, and Ligonier districts, Pa., in 1917–18.

FAIRMONT DISTRICT, W. VA.

Increased shipments eastward and decreased shipments westward characterized the distribution of coal from the Fairmont district in 1918, compared with 1917. From April 1 through the year the Fuel Administration permitted only such portion of the output from this district to move west (except to the Lakes for cargo) as could not be handled by the railroads for eastern markets. Shipments to Illinois, Indiana, Michigan, and Ohio were materially reduced. The increase in total production of nearly 2,600,000 tons was largely taken by the railroads and shipped to tidewater or to the Lakes for cargo. Eastern Pennsylvania is the best all-rail market for this district, next to which come New Jersey and Ohio. Little of the coal from the district is sold to retailers for the domestic trade, and but relatively small quantities to public utilities. The railroads and industrial plants are the principal consumers of coal from the Fairmont district.

Distribution of coal produced in Fairmont district, W. Va., in 1917–18.

NEW RIVER FIELD, W. VA.

The limitations placed on westbound shipments of the smokeless coal produced in the New River field by the zone system is reflected in the statistics of distribution for 1918, compared with 1917. Shipments to Illinois decreased from 275,000 net tons in 1917 to about 11,000 tons in 1918, and the decrease in shipments to Indiana, Michigan, and Ohio ranged from about 50 to more than 80 per cent. Shipments to Virginia were more than doubled, and increased quantities of New River coal were supplied to North Carolina and South

Carolina and to the railroads for fuel. Tidewater dumpings of New River coal were slightly greater in 1918 than in 1917, but shipments to lower Lake Erie ports declined from 578,000 to 361,000 tons. The record for 1918 was largely determined by the policy of the Fuel Administration, which, after April 1, 1918, directed the movement. Smokeless coal from southern West Virginia was reserved for tidewater business and diverted from the New River field in large measure to supply the needs of industry and the householder in Virginia and the Carolinas, which constitute what is known as the "inland east" market. The coal from this field that moved westward after April 1, 1918, was shipped under permit for special purposes, as the manufacture of by-product coke and smithing.

Distribution of coal produced in New River field, W. Va., in 1917–18.

POCAHONTAS AND TUG RIVER FIELDS, W. VA.

The control of the distribution of Pocahontas coal was one of the most important items in the program of the Fuel Administration. From this field comes largely the low-volatile coal that is so essential to the manufacture of by-product coke and the fuel for bunkering ships. Before the war Pocahontas coal was used extensively as domestic fuel in the Middle West, notably in Chicago and in Ohio and Michigan. New England had been a large consumer of smokeless coal from both the Pocahontas and the New River fields. The great growth of the by-product coke industry, particularly in Ohio, Illinois, and Indiana, the enlarged demands of the Army and the Navy transport service, and the new burden of supplying the immense

powder plant at Hopewell, Va.—a single requirement of 1,500,000 net tons annually—necessitated the curtailment of the use of Pocahontas coal in other directions.

By denying this coal to Chicago and vicinity, except for making by-product coke, the rail movement to Illinois was decreased from 2,650,000 tons in 1917 to 969,000 tons in 1918. More than half of the coal thus made available was absorbed by the coke ovens in Indiana. The use of smokeless coal for domestic purposes was prohibited in the Northwest, and the Lake cargo shipments were reduced nearly 1,000,000 tons. Shipments to Ohio and Michigan were almost entirely confined to coal for special uses and were made only by permit, with the result that each of those States received much less Pocahontas coal in 1918 than in 1917. On the other hand, increased quantities were supplied to North Carolina and South Carolina, Maryland, and the District of Columbia.

The gain in tidewater shipments of about 1,500,000 tons, or nearly 25 per cent, was a necessary part of the Fuel Administration's program, and was accomplished despite a decline in total production of 1,800,000 tons, or 7 per cent.

Distribution of coal produced in Pocahontas and Tug River fields, W. Va., in 1917–18.

SOUTHWESTERN VIRGINIA.

The principal features of the distribution of coal from southwestern Virginia in 1918 were the more or less widespread shipments of coal for special uses, as gas making, by permit under the zone system of the Fuel Administration, and the increased shipments to southern markets to supplement the decreased supplies from Alabama. Deliveries to consumers in Florida, Georgia, North Carolina, and South Carolina, and to the railroads for fuel, increased, but deliveries to tidewater decreased slightly. Deliveries to retail dealers were about the same as those to public utilities and not much less than deliveries to industrial consumers.

SOMERSET AND CUMBERLAND-PIEDMONT DISTRICTS, PA., MD., AND W. VA.

In order of quantity taken the principal markets reached by coal from the Somerset-Cumberland-Piedmont field are tidewater, Pennsylvania, Maryland, New Jersey, the District of Columbia, and the railroads for fuel. Smaller quantities go to other States, both near and far. The well-known Georges Creek blacksmithing coal is produced in the Cumberland-Piedmont district and in normal times is widely distributed.

ALABAMA.

The program of the Fuel Administration did not contemplate material reduction in 1918 of the area in which coal from Alabama is normally distributed but rather planned to take care of the industrial and other needs of the State of Alabama primarily with Alabama coal and to supplement the shipments from this State to other near-by markets that are normally dependent on coal from Alabama by supplies from other fields, such as Tennessee, Virginia, and western Kentucky. How this program worked out is shown by the statistics of distribution for 1917 and 1918. As in 1917, more than half the coal produced in Alabama in 1918 was used in the State. With the exception of those to Florida, shipments to all other States were less in 1918 than in 1917, as were deliveries to railroads. The special efforts of the Fuel Administration to increase the use of Alabama coal at tidewater points, for the relief of northern ports, resulted in an increase of deliveries to tidewater of more than 200,000 tons.

TENNESSEE AND GEORGIA.

The control exercised by the Fuel Administration in 1918 had the effect of concentrating the distribution of coal from Tennessee in a smaller area than was recorded for 1917. Illinois, Iowa, Minnesota, Missouri, Texas, and Wisconsin, to which shipments were made in 1917, received no coal from this field in 1918, and the deliveries to consumers in Arkansas, Indiana, Kentucky, Louisiana, Michigan, and notably Ohio were reduced as a result of the requirements of the Fuel Administration that the coal be shipped to southern markets.

CONNELLSVILLE DISTRICT, PA.

The Connellsville district is preeminently a source of beehive coke and of late years has been a source of coal for the manufacture of by-product coke. More than 79.3 per cent of the coal produced in this district is used in Pennsylvania, largely in the manufacture of coke at the mines, and the greater part of that shipped goes to by-product coke-oven plants and industries requiring a gas coal of high grade. Less Connellsville coal (including that coked at the mines) was used in Pennsylvania in 1918 than in 1917, owing to a lessened use of beehive ovens, the coal coked at the mines decreasing nearly 2,000,000 tons. Shipments to consumers in Pennsylvania increased nearly 50 per cent, and shipments in 1918 to consumers in New Jersey, New York, and Ohio (where the manufacture of by-product coke was being rapidly developed) were in excess of those in 1917.

PITTSBURGH, PA., AND PANHANDLE OF WEST VIRGINIA.

There were no material changes in the distribution of coal from the Pittsburgh district in 1918. Approximately the same quantities were supplied to the more important markets in 1918 as in 1917, except New Jersey and New York, which received decreased shipments. One-half of the increase in total production was taken by the railroads, which use about 10 per cent of the coal from this field. The principal markets are railroad fuel, the Northwest by way of the Great Lakes, Canada, Pennsylvania, New Jersey, New York, and Ohio. The Pittsburgh industrial district is of course the largest single market, and in western Pennsylvania coal from the Pittsburgh district is used for domestic purposes and by public utilities.

NORTHERN OHIO.

The increase of 3,400,000 tons in production in 1918 in the fields here designated northern Ohio was largely delivered to consumers in Ohio, Michigan, Canada (by rail), and the Northwest (by way of the Great Lakes). To make available additional coal for the Lakes the Fuel Administration arranged in the summer of 1918 for the transfer of certain railroad requirements from Ohio to Indiana, which accounts for the decrease in deliveries of railroad fuel coal from northern Ohio.

SOUTHERN OHIO.

The distribution of coal from southern Ohio in 1918 was, by the zones established by the Fuel Administration, confined within narrower limits than in 1917. This was particularly true as regards Michigan, from the western fourth of which southern Ohio coal was excluded, and for a part of the year this coal, except for domestic consumers, was excluded from the other States which it reaches under normal conditions. The prohibition of shipments to eastern Indiana does not appear to have affected the distribution to any great extent, as the shipments to Indiana in 1918 amounted to 147,000 tons, compared with 162,000 tons in 1917. Notwithstanding the restriction in movement of Ohio coal to Michigan, the southern Ohio district recorded a gain in that market. A substantial increase in shipments to consumers in Ohio was also recorded. Shipments to the Lakes for cargo were increased more than 300,000 tons, as a result of the restrictions of distribution into Michigan placed by the Fuel Administration and of certain transfers of requirements of railroad fuel from the southern Ohio district to Indiana fields. In other words, the gain in Lake shipments was effected, at least in part, by a decrease in deliveries to railroads for fuel.

MICHIGAN.

Coal from mines in Michigan to the extent of nearly 200,000 tons more than in 1917 was delivered to consumers in the State in 1918, as a result of a slightly greater production and a decrease in the deliveries to railroads for fuel.

Distribution of coal produced in Michigan in 1917–18.

NORTHEASTERN KENTUCKY.

The coal from northeastern Kentucky in 1918 was distributed largely in the same markets as in 1917, with the difference, however, that within those market areas the coal was to a considerable extent diverted from steam and domestic uses to manufacturers of by-product coke and other consumers of high-grade gas coal. A small increase in production and decreased shipments to Illinois, Iowa, Kansas, Minnesota, Nebraska, North Carolina, South Dakota, Tennessee, and Wisconsin furnished increased supplies for Indiana, Kentucky, Michigan, Ohio, and Canada, where coal of the special quality produced in this field was needed for such purposes as the manufacture of by-product coke.

SOUTHEASTERN KENTUCKY.

One of the effects of the control by the Fuel Administration in 1918 of the distribution of coal from southeastern Kentucky was the reduction in movement to such Central States as Iowa, Kansas, South Dakota, and Minnesota, and increases to markets in the South—Florida, Georgia, Tennessee, North Carolina, and South Carolina—and in the North—Illinois, Indiana, Michigan, and Ohio. A considerable portion of the commercial shipments from this field go to retail dealers, and except the gas coal for the manufacture of by-product coke and other special uses and railroad fuel, coal for domestic use forms the largest item in the output from this district.

Distribution of coal produced in southeastern Kentucky in 1917–18.

KANAWHA AND KENOVA-THACKER DISTRICTS, W. VA., KY.

The effect of the control exercised by the Fuel Administration in 1918 on the distribution of coal from the Kanawha and Kenova-Thacker districts is indicated in the following table. In 1917 shipments were made to 18 States (other than West Virginia and Kentucky, where the coal is produced); in 1918 to 12 States. No all-rail shipments were made in 1918 to Delaware, Minnesota, Missouri, Nebraska, New York, or South Dakota, each of which received coal from this field in 1917. Shipments to all other Central States, as Illinois, Iowa, and Wisconsin, were limited to coal for special purposes and were less in 1918 than in 1917. There were notable increases in the movement of coal from these districts to Michigan and Ohio, on the west, mainly in coal for domestic use. About one-fourth of the coal sold through retailers in Michigan and nearly one-fifth of that sold in Ohio in 1918 came from these districts. Of the all-rail commercial shipments, about 22 per cent is sold to retail dealers.

WESTERN KENTUCKY.

Compared with 1917, there were reductions in the shipments of coal from western Kentucky in 1918 to markets in Alabama and Texas in the South, and to Illinois, Indiana, Iowa, Missouri, Nebraska, South Dakota, and Wisconsin, in the North and West. Shipments to Ohio were also less in 1918 than in 1917. These reductions were due to the policy of the Fuel Administration of confining the distribution of coal from the western Kentucky field generally to southern markets. Notable increases in deliveries to consumers in Mississippi and Tennessee and small gains in Arkansas and Louisiana were recorded in 1918. The largest increase was in the deliveries of coal to railroads, which showed a gain of 41 per cent.

INDIANA.

Notable increases in the shipment of coal from Indiana to consumers in the State, to Illinois and Michigan, and to the railroads for fuel were made in 1918. The increase in total production of more than 4,000,000 tons was distributed in the markets named. The States to which, either in whole or in part, coal from Indiana was denied by the Fuel Administration under the zone plan, as Iowa, Minnesota, and Missouri, are shown in the following table to have received less coal from this State. The small shipments recorded were either delivered before the zone system became effective on April 1, 1918, or were forwarded under permit for special purposes. Deliveries to retail dealers represent an important part of the business of the shippers of coal from Indiana, and during the summer and early fall of 1918 these deliveries were larger than normal, but they decreased after the armistice was signed and during the mild winter.

Distribution of coal produced in Indiana in 1917–18.

ILLINOIS.

The production of coal in Illinois increased in 1918, compared with 1917, by more than 3,000,000 tons. For consumers in the State of Illinois deliveries were greater in 1918 by about 5,700,000 tons; total commercial shipments to other States were about the same in the two years, but deliveries to railroads were more than 3,000,000 tons less in 1918 than in 1917. A considerable portion of the coal in commercial shipments from Illinois normally goes to retail dealers, and in September and October that trade represented nearly half of the total.

ARKANSAS.

The distribution of coal produced in Arkansas for nine months of 1918, under the control of the Fuel Administration, was not greatly different from that recorded for 1917. Shipments were confined largely to markets nearer the mines, however, and no coal was shipped to such distant points as Minnesota.

Distribution of coal produced in Arkansas in 1917–18.

	Quantity (net tons).		Percentage of total.	
	1917	1918	1917	1918
Used in Arkansas:

	2,143,579	2,227,369	100.0	100.0

IOWA.

The decrease in the production of coal in Iowa in 1918 was due largely to lack of demand from the railroads. Deliveries of Iowa coal for railroad fuel in 1918 showed a decrease of 700,000 tons. The prohibition of shipments of eastern coal west of the area immediately adjacent to the Mississippi gave shippers in Iowa opportunity to extend their markets. In 1918 Iowa coal was shipped to 10 other States, compared with 5 in 1917.

Distribution of coal produced in Iowa in 1917–18.

MISSOURI.

There was little change recorded in the distribution of coal from Missouri in 1918, compared with 1917. Deliveries to consumers in Missouri declined, but shipments to other States increased, especially those to Arkansas, Iowa, Kansas, and Nebraska. Deliveries to the railroads were about the same in both years.

Distribution of coal produced in Missouri in 1917–18.

KANSAS.

Deliveries of coal produced in Kansas to consumers in that State in 1918 were slightly less than in 1917, but shipments to other States, as Missouri, Nebraska, and Oklahoma, increased. The consumption of coal from Kansas by the railroads was about the same in both years.

Distribution of coal produced in Kansas in 1917–18.

OKLAHOMA.

Coal produced in Oklahoma and delivered to consumers in that State increased in 1918, and shipments to other States, particularly Arkansas, Kansas, Nebraska, New Mexico, and Texas, were also greater. The railroads used less coal from Oklahoma in 1918 than in 1917.

Distribution of coal produced in Oklahoma in 1917–18.

COLORADO.

The coal produced in Colorado in 1918 was more generally distributed outside the State than in 1917. Less coal from mines within the State was used in Colorado in 1918, but shipments to the railroads for fuel, and to certain other States increased. Among the States receiving increased quantities of Colorado coal were Iowa, Kansas, Nebraska, Oklahoma, and Texas.

Distribution of coal produced in Colorado in 1917–18.

	Quantity (net tons).		Percentage of total.	
	1917	1918	1917	1918

[a] Includes approximately 1,215,000 tons of coal shipped to beehive coke ovens.

NEW MEXICO.

Increases in deliveries to consumers in New Mexico and in commercial shipments to other States are recorded in the distribution of coal produced in New Mexico in 1918. Deliveries to the railroads for fuel declined, but exports by rail (to Mexico) increased. Shipments to tidewater (Pacific coast ports) decreased.

Distribution of coal produced in New Mexico in 1917–18.

	Quantity (net tons).		Percentage of total.	
	1917	1918	1917	1918
Used in New Mexico:

[a] Includes approximately 533,000 tons of coal shipped to beehive coke ovens.

NORTH DAKOTA.

Lignite produced in North Dakota is almost entirely used within the State. About 4,300 tons was shipped to Minnesota in 1918; no shipments to that market were recorded in 1917.

Distribution of coal produced in North Dakota in 1917–18.

	Quantity (net tons).		Percentage of total.	
	1917	1918	1917	1918
Used in North Dakota:

MONTANA AND NORTHERN WYOMING.

The distribution of coal from Montana and other Rocky Mountain and Pacific Coast States was in no way regulated by the zone system of the Fuel Administration. Increased quantities of coal from those fields were supplied in 1918, compared with 1917, to Montana, Wyoming, North Dakota, and South Dakota, as well as to the railroads for fuel. Shipments were made in 1918 to Colorado, Kansas, Minnesota, and Oregon; none of these States received coal from this region in 1917.

Distribution of coal produced in Montana and northern Wyoming in 1917–18.

	Quantity (net tons).		Percentage of total.	
	1917	1918	1917	1918

UTAH AND SOUTHERN WYOMING.

The increase in the use of coal from Utah and southern Wyoming in 1918, compared with 1917, was general. The only States to which decreased shipments were made in 1918 were Iowa, Montana, and Nebraska. The railroads received over 18 per cent more than in 1917, and shipments to tide water (San Francisco) more than tripled.

Distribution of coal produced in Utah and southern Wyoming in 1917–18.

	Quantity (net tons).		Percentage of total.	
	1917	1918	1917	1918
Used in Utah:

Shipped to tidewater	22,861	69,884	.23	.61
	9,899,008	11,501,890	100.00	100.00

WASHINGTON.

The coal produced in Washington is used principally within the State, in Oregon, by the railroads, and for bunkers at tidewater in Puget Sound. Decreases in the demand in Oregon and by the railroads in 1918 were offset by increased demand in Washington and at tidewater, with the result that the production in 1918 was almost identical with that in 1917.

Distribution of coal produced in Washington in 1917–18.

	Quantity (net tons).		Percentage of total.	
	1917	1918	1917	1918
Used in Washington:

	4,009,902	4,082,212	100.0	100.0

EXPORTS AND IMPORTS.

Exports of bituminous coal in 1918 were 22,350,730 net tons, compared with 23,839,558 tons in 1917 and 21,254,627 tons in 1916. Exports to Europe were but 48,563 tons, almost a negligible quantity compared with 996,957 tons in 1917 and more than 2,500,000 tons in 1916. This decrease in exports of coal to Europe was due to no lack of demand but to the necessity for the conservation of shipping for strictly war purposes.

Exports of bituminous coal to Canada amounted to 18,134,328 net tons, approximately the same as in 1917. Exports to South America declined slightly, from 1,605,781 net tons in 1917 to 1,465,439 tons in 1918. The statistics of exports and imports in the accompanying table are taken from the records of the Bureau of Foreign and Domestic Commerce of the Department of Commerce.

Coal exported from the United States, in 1916–1918, by countries, in net tons.

CONSUMPTION OF BITUMINOUS COAL AND LIGNITE BY INDUSTRIES, ACCORDING TO SOURCES.

COAL USED BY RAILROADS.

The statistics of the consumption of coal by railroads were collected in 1917 and 1918 in a different form from that used in 1915 and 1916. To increase both the ease of compilation of the data by the railroads and the accuracy of the figures, the origin of the coal delivered for consumption was requested rather than the origin of the coal consumed.

A comparison of the statistics showing the origin of coal used for railroad fuel for the years 1915, 1916, and 1917 will be found in the report on the distribution and consumption of coal for 1917.[1] In the present report a summary of the statistics for 1918 only is included. The tables of the statistics on deliveries and consumption of coal by railroads, by classes of roads, will be found in Part III of the report of the Distribution Division, United States Fuel Administration. The data here given are summarized from those contained in the report of the Fuel Administration, revised and corrected in final form.

a Included with Kanawha (Chesapeake & Ohio).

COAL USED BY STEAMSHIPS.

The following statistics of bunker coal supplied to steamships engaged in foreign commerce are derived from the records of the Bureau of Foreign and Domestic Commerce. They do not include bunker coal delivered to the Army or Navy transport service in 1918. It was the policy of the Treasury Department and the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, to consider shipments of goods to France or elsewhere for the use of the Army or Navy as domestic consumption, and not as exports; likewise, the coal used by the vessels under these services was considered as domestic bunker coal.

The statistics of bituminous coal shipped to tidewater and used for coastwise and local bunker purposes and for the Army and Navy transport service will be found in a previous section of this report dealing with the shipments of coal to tidewater.

Bunker coal supplied to steamers engaged in foreign trade at ports of United States, 1916–1918, in net tons.

COAL USED BY INDUSTRIES.

The statistics given in the following table show the quantities of bituminous coal used in 1918 at the coal mines for steam and heat and used in the manufacture of beehive coke, of by-product coke, and of coal gas (in bench retorts), by States in which the coal was consumed. These data are compiled from reports made directly to the Geological Survey by the consumers. The figures for the total coal consumed in each State, exclusive of railroad fuel and bunker coal, are derived from

the records of the Fuel Administration, which, however, do not furnish sufficient detail to permit a separation of the coal used by electric utilities, for industrial purposes, and for domestic purposes, such as is shown in the report on the distribution and consumption of coal in Mineral Resources for 1917. The reports of the Distribution Division, United States Fuel Administration, particularly Part III, contain the greater part of the detailed data on the consumption and use of bituminous coal collected by the Fuel Administration.

Bituminous coal of domestic origin consumed in the United States in 1918, in net tons.

[Railway fuel and bunker fuel for ocean vessels not included in this table.]

State.	Used at mines for steam and heat.	Used in manufacture of beehive coke.	Used in manufacture of by-product coke.	Used in manufacture of coal gas.	Used for domestic and industrial purposes, including electrical utilities.	Total coal consumed.

[a] Included in quantity shown for States as used for domestic and industrial purposes and in total of combined States.
[b] Includes coal used for manufacture of coal gas.
[c] Includes coal used for manufacture of by-product coke.
[d] Includes coal used for manufacture of coal gas and beehive coke.
[e] Includes coal used for manufacture of beehive coke.
[f] This total, which represents the net quantity used for domestic and industrial purposes, does not include 814,707 tons used in the manufacture of beehive coke, 3,090,738 tons used in the manufacture of by-product coke, and 55,311 tons used in the manufacture of coal gas, but these quantities are included in the detailed figures by States.

CONSUMPTION OF BITUMINOUS COAL, BY STATES.

The statistics given below showing the sources and quantity of bituminous coal received in each State do not represent consumption but rather quantities delivered and available for consumption. Consumption was greater or less than deliveries by the quantity of coal put into or taken from storage. Statistics collected by the Fuel Administration in 1918 show clearly that the quantity of bituminous coal in storage in the hands of the consumers was much greater at the end of 1918 than at the beginning, although exact figures are not available, because no comprehensive statistics of stocks as of the beginning of 1918 were collected.

The tables showing coal consumed in different States in 1918 are followed by two tables showing the percentages of distribution, by classes of users, of coal shipped from each producing district and received in each consuming State. These percentages are based upon weekly reports made by operators producing 95 per cent of the coal produced in the United States in the period of 27 weeks from August 3, 1918, to February 1, 1919.

Coal consumed in different States in 1918, in net tons.

DISTRIBUTION OF BITUMINOUS COAL, BY CLASSES OF CONSIGNEES.

The foregoing statistics give the distribution of bituminous coal geographically. From August 3, 1918, to February 1, 1919, the United States Fuel Administration maintained records of shipments from each producing field to certain classes of consumers, representing the order of preference to which coal was supplied under the war program of the Fuel Administration. These statistics will be found in complete detail in Part III of the report of the Distribution Division of the Fuel Administration. As a matter of reference, in connection with the statistics of geographic distribution by States contained in the preceding tables in this report, the two following tables are presented, giving the distribution by classes of consignees. The first table shows the percentages of coal consigned to each State, by classes of consumers. The second table shows the percentage of coal from each producing field consigned to each class of consumers in all the States to which that field made shipment. In the detailed statistics given in the report of the Fuel Administration will be found the data showing percentages of shipment from each field to each class of consumers in each State.

It should be noted that the first class of consumers mentioned, the United States Government, received in all probability a larger percentage of total shipments in 1918 than might be considered normal, owing, of course, to the war activities. The percentages to State and county institutions are probably not far from normal, but the percentages to public utilities and to retail coal dealers are lower than they would be if an entire calendar year were represented in the figures.

Distribution of all-rail shipments of bituminous coal from Aug. 3, 1918, to Feb. 1, 1919, by consuming States and classes of consignees.

Consuming State.	Percentages of shipments to classes of consignees.

PRODUCTION OF BITUMINOUS COAL, BY CHARACTER OF OPENING AND BY BED OR SEAM.

Schedules furnished to the operators of bituminous coal mines by the Geological Survey on which to report their production in the calendar year 1918 made inquiry as to the character of the mine opening—that is, whether shaft, slope, drift, or strip pit—and also the name or number or other local term applied to the coal bed from which the coal was produced.

The mines were classified into five classes in accordance with the output, and the total production of each class in each State is shown in the following table together with the total number of mines in each class and the number of mines operated through shaft, slope, drift, or as open pit. The first class is that of mines producing more than 200,000 tons in 1918; the second, those producing from 100,000 to 200,000 tons; the third, those producing from 50,000 to 100,000 tons; the fourth, those producing from 10,000 to 50,000 tons; and the fifth, those producing less than 10,000 tons.

It will be noted that in the Mississippi Valley, Illinois, Indiana, and western Kentucky in particular, shaft mines predominate, and that in the Appalachian regions drift mines predominate. Slope mines predominate in Oklahoma, Washington, and Wyoming.

Considerable difficulty has been experienced in tabulating the production by name or number of bed. This difficulty doubtless arose from the fact that many operators know none other than a purely local name for the coal bed on which they are operating. In many fields correlations have not been made by officials of either the State survey or the Federal Survey, and there is no proper way by which the operator can correctly determine the name and number of bed on which he is operating. The same bed may be known by different names in the same field, and to have listed the record throughout as it was submitted by the operator would have made more confusion in the final tabulation. M. R. Campbell, of the United States Geological Survey, examined the returns from the operators for Alabama, Arkansas, Routt County, Colo., Illinois, Ohio, and Pennsylvania. He had the assistance of geologists in the Survey who are familiar with the different fields in these States, and ambiguities and duplications were eliminated by them. The reports indicate that in the far West and in some of the Eastern States, as Michigan, and in the South, in Texas, nearly every mine has its own name for the bed on which it is being operated, so that the tabulation of the returns from these States would simply be a list of names, one for each mine, with the production as reported. These tables have not been included in this report because they are not considered to be significant or to be of any value. The data for Indiana were compiled by Mr. Jonas Waffle, secretary of the Indiana Coal Trade Bureau.

PRODUCTION OF BITUMINOUS COAL, BY SIZE OF MINES.

Reports of production were received by the Geological Survey for 11,038 bituminous coal mines in 1918, compared with 10,634 mines in 1917. The increase occurred principally in mines producing from 10,000 to 50,000 tons, and mainly in Kentucky, Ohio, Pennsylvania, and West Virginia. Statistics showing the production by size of mines for 1917 and 1918 are contained in the following tables. These statistics properly belong in Part A of the report on coal, but were delayed in preparation and are accordingly included in this part.

Bituminous coal produced in the United States in 1917, according to classes of mines.

State	First class (mines producing more than 200,000 tons).					Second class (mines producing from 100,000 to 200,000 tons).					Third class (mines producing from 50,000 to 100,000 tons).				
	Mines.		Quantity.			Mines.		Quantity.			Mines.		Quantity.		
	Number.	Percentage.	Total (net tons).	Average per mine (net tons).	Percentage.	Number.	Percentage.	Total (net tons).	Average per mine (net tons).	Percentage.	Number.	Percentage.	Total (net tons).	Average per mine (net tons).	Percentage.

NATURAL GAS.[1]

By E. G. Sievers.

PRODUCTION.

The peak of the production of natural gas in the United States was reached in 1917, the production in 1918 being 9 per cent less in volume, a decline which was probably continued during 1919. The total output in 1918 was 721,000,959,000 cubic feet, a decrease of 74,109,417,000 cubic feet, which is accounted for by the falling off in West Virginia, Oklahoma, Pennsylvania, Ohio, and California.

Twenty-seven States produced natural gas in 1918. The chief producing States, in the order of output, were West Virginia, Oklahoma, Pennsylvania, Ohio, California, Louisiana, Kansas, and Texas. Of the producing States 8 increased in output, 15 decreased, and 4 were credited with a production for the first time.

Despite the decrease in output in 1918 the market value was $153,553,560, a gain of $11,464,226, or 8 per cent, over the value in 1917. The average price in 1918 at the point of consumption was 21.29 cents per thousand cubic feet, a gain of 3.42 cents, or 19 per cent.

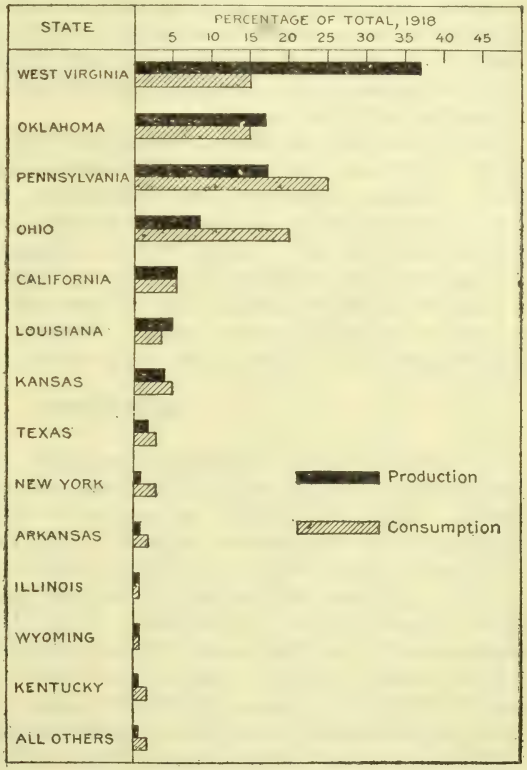

FIGURE 118.—Distribution by States of the natural gas produced and consumed in the United States in 1918.

At the end of 1918 there were 40,369 wells producing natural gas, a little over 1,000 more than at the end of 1917. Activities during 1918 resulted in the drilling of 5,316 wells, of which 3,808, or 72 per

[1] The statistical tables were compiled by Miss M. E. Cox, of the United States Geological Survey. The preparation of this report has been unavoidably delayed. Only a summary statement is presented, therefore, in addition to the tables.

cent, were successful gas wells, and 1,508, or 28 per cent, were dry. A total of 2,722 wells were abandoned during the year.

At the end of 1918 the total acreage of natural-gas lands, including reserves, was 14,578,056 acres, which was 866,093 acres less than at the end of 1917.

CONSUMPTION.

GENERAL.

One of the most interesting as well as important features of the consumption of natural gas in 1918 was the increased use for domestic purposes—lighting, heating, and cooking—and the decreased consumption in the industries. This result is directly in line with the aims of the conservation movement, namely, to curtail the quantity of gas entering the industries and thus leave a greater supply for domestic consumption, and one of the factors causing this result was the restriction by some State public-service commissions of industrial sales of gas between November 1 and May 1. During the summer, when the demand for domestic gas drops, more gas is again sold to industrial establishments.

The principal consuming States in 1918 were Pennsylvania, Ohio, West Virginia, Oklahoma, California, Kansas, Louisiana, New York, Texas, Arkansas, and Kentucky, which together consumed 701,068,684,000 cubic feet of natural gas, or 97 per cent of the total consumption in the United States. Approximately 78 per cent of the natural gas produced in 1918 was consumed in the States where it was produced, the remaining 22 per cent being piped out for consumption in neighboring States. Pennsylvania alone consumed 25 per cent and Ohio 20 per cent of the total in 1918.

DOMESTIC.

In 1918 2,508,543 domestic consumers used 271,102,298,000 cubic feet of gas, or 38 per cent of the total volume consumed in the United States. This was a gain, as compared with 1917, of 3 per cent in the number of consumers and of 5 per cent in the quantity of gas consumed, which bears out the increased tendency already referred to for a greater utilization of natural gas for domestic purposes. Ohio, Pennsylvania, Oklahoma, West Virginia, New York, and Kansas are the largest users of the domestic gas.

The market value of the natural gas used for domestic purposes was $85,003,742, a gain of $5,580,113, or 7 per cent. The average price per thousand cubic feet of domestic gas in 1918 was 31.35 cents, slightly more than the average price in 1917.

The average annual consumption per domestic consumer was 108,000 cubic feet and the average monthly consumption was about 9,000 cubic feet, practically the same as in 1917.

INDUSTRIAL.

Industrial establishments numbering 16,581 in 1918 consumed 449,898,661,000 cubic feet of natural gas, or 62 per cent of the total consumption in the United States. Of these establishments, 82 per

cent were in Pennsylvania, Ohio, West Virginia, Oklahoma, California, and Kansas, and they consumed 86 per cent of the total industrial gas used in the United States. A decrease of 11 per cent in the number of industrial consumers and of 16 per cent in the volume of gas utilized in the industries in 1918 shows the results of the policy of curtailing the use of natural gas in industrial plants. About 261,278,897,000 cubic feet, or 58 per cent of the gas utilized for industrial purposes in 1918, was consumed in manufacturing, in furnaces, kilns, and ovens, in the manufacture of brick, cement, pottery, and glass, and in the smelting of ores. The remaining 188,619,764,000 cubic feet, or 42 per cent, was used as fuel in the generation of power. Of the total number of industrial consumers, 5,986 used natural gas in manufacturing and 10,595 used gas for generating power.

The market value attributed to the total volume consumed in the industries in 1918 was $68,549,818, of which $45,913,824 was the value of the natural gas used in manufacturing and $22,635,994 that of the gas used for power.

The average consumption of natural gas per industrial consumer was 27,133,000 cubic feet annually and 2,261,000 cubic feet monthly.

Natural gas produced and consumed in the United States in 1917.

a Includes some gas piped from Oklahoma to Missouri.
b Includes some gas piped from West Virginia to Maryland.
c Includes some gas piped from Kansas to Missouri.
d Includes some gas piped to Texas and to Arkansas from Louisiana.
e Includes some gas piped from Illinois to Vincennes, Ind.
f Includes some gas piped from Oklahoma to Arkansas.

NATURAL-GAS GASOLINE.

By E. G. Sievers.[1]

INTRODUCTION.

GENERAL STATEMENT.

The term "natural-gas gasoline," as used by the United States Geological Survey, includes the gasoline recovered by all methods from both "wet" and "dry" natural gas and is synonymous with the term "casing-head gasoline," which is largely used in the industry. The terms "raw" and "unblended" gasoline are used interchangeably in this report, and "commercial" gasoline is the term applied to gasoline that has been blended with naphthas or distillates.

The completion of this report has been made possible by the hearty cooperation of the producers.

GROWTH OF THE INDUSTRY.

The natural-gas gasoline industry has made large contributions to the supply of motor fuel and has achieved remarkable advances since its beginning. In increasing the supply of motor fuel natural-gas gasoline is a direct means of conservation in that its extraction does not destroy the gas in which it is contained. Experiment has demonstrated that the extraction of gasoline from natural gas does not reduce appreciably the value of the gas for heat, power, and light, but that it is a benefit, for it removes not only the water but also the gasoline, which causes leakage by disintegrating the rubber gaskets in the pipes. Statistics covering the eight years from 1911 to 1918, inclusive, show that an estimated volume of 1,145,113,000 thousand cubic feet of natural gas was treated during that time in the manufacture of gasoline and that the total quantity of gasoline obtained was approximately 755,497,000 gallons. After furnishing this supply of gasoline, the natural gas treated was sent through transmission lines to distributing companies or direct to the consumers and utilized for fuel and light. The industry may therefore be compared favorably with the carbon-black industry, in which the natural gas is destroyed.

The natural-gas gasoline industry has also brought the oil and gas producers on the one hand and the refiners on the other into a closer relationship than existed prior to its development. The high volatility of natural-gas gasoline makes it necessary to reduce its gravity by blending with distillates or naphthas. These products formerly overstocked the refiner, but now that their use in this industry is

[1] The statistical tables in this report were compiled by Miss J. R. Penner, of the United States Geological Survey.

becoming so large the supply is unequal to the demand. At the very outset of the industry it was demonstrated that the blending of the casing-head gasoline with heavier products, such as naphthas, was practicable. The naphthas and distillates alone had no great commercial use. They could not be used satisfactorily as a motor fuel because they were deficient in low-boiling fractions. The mixing of these products with natural-gas gasoline resulted in a well-balanced, ideal motor fuel.

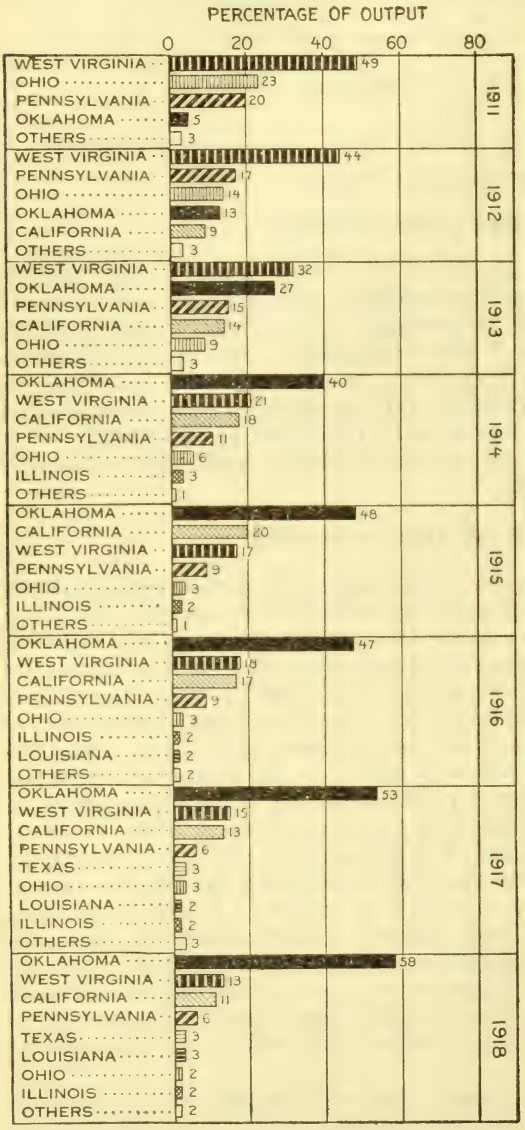

FIGURE 119.—Natural-gas gasoline produced in the United States, by States, 1911–1918.

The experiments of Fasenmeyer near Titusville, Pa., of Tompsett Bros. near Tidioute, Pa., and of Sutton Bros. at Sistersville, W. Va., as far back as 1903, laid the foundations of the natural-gas gasoline industry. Between 1905 and 1908 renewed efforts in experiments pertaining to the industry were made by Richards at Mayburg, Pa., Hollingshead at Bradford, Pa., McCarty at Bolivar, N. Y., Gray at Kinzua, Pa., and others. It was not until after 1909, however, that the industry was placed on a commercial basis.

Casing-head gasoline is extracted from natural gas chiefly by two methods, the compression method and the absorption method. Prior to 1916 the greater portion of the gasoline was recovered by the compression and vacuum-pump method from the "wet" gas obtained from oil wells. The largest output came from plants specially designed and installed for the recovery of the gasoline vapors in the gas of that type, but a certain proportion, especially in the Appalachian oil field, was incidentally recovered by the use of simple condensing apparatus connected with vacuum pumps installed to ex-

pedite the production of oil. Some gasoline was recovered as drips from gas-transmission lines.

The development of the absorption process through research work done in 1912 and 1913 by G. M. Saybolt, a chemical engineer of the Hope Natural Gas Co., Pittsburgh, Pa., has been the chief means of increasing the production of casing-head gasoline. The introduction of this process has made it commercially possible to extract gasoline from "dry" gas that contains too little gasoline to warrant treatment by compression methods.

Although increasing the production of gasoline has been the paramount aim of those engaged in the industry, some attention has been given to the possibility of recovering liquid propane and butane in the process of extracting gasoline. The feasibility of recovering these substances has been shown both by experiments and by actual production. Liquid propane and butane have higher fuel values than natural gas, and their usefulness in cutting and welding metals, in heating and lighting, and as a source of power in stationary and automotive combustion engines has been demonstrated.

The natural-gas gasoline industry has grown rapidly. The first statistics of production collected, those for 1911, showed that 7,425,839 gallons of raw gasoline were in that year recovered at 176 plants in 9 States. During the eight years from 1911 to 1918 there was an increase of 470 per cent in the number of plants and of about 3,700 per cent in the production of raw gasoline. The marked increase in production in 1916 and 1917 was due to a greater demand for gasoline. This resulted in increased activity in plant construction and development, improvement of plant efficiency, and the treatment of a greater volume of natural gas. The rapid expansion of the industry is shown by the accompanying diagrams (figs. 119–122).

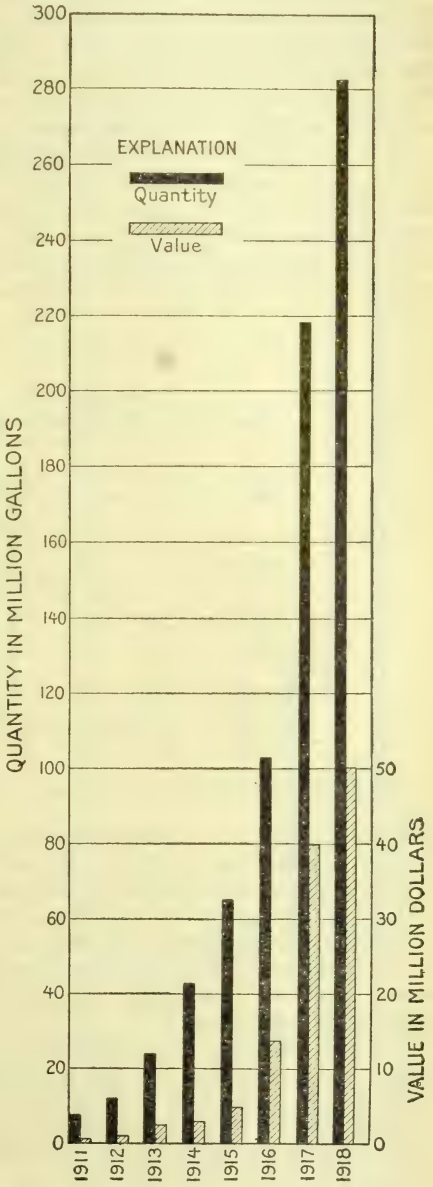

FIGURE 120.—Quantity and value of natural-gas gasoline produced in the United States, 1911–1918.

PRODUCTION.

GENERAL STATEMENT.

The quantity of natural-gas gasoline produced in 1918 was about 30 per cent greater than that produced in 1917; the increase in 1917 over 1916 was 110.5 per cent. The total quantity of raw gasoline recovered in 1918 was 282,535,550 gallons, including that contributed by compression and vacuum pumps and by absorption and that recovered as drips from gas mains. In 1918 the compression plants, which are by far the largest producers, yielded 219,767,207 gallons, or 77.8 per cent of the total production. This quantity was 50,900,652 gallons, or 30.1 per cent, more than that supplied by the compression plants in 1917. The remaining 62,768,343 gallons, or 22.2 per cent of the total, was the product of the absorption plants and included drip gasoline collected from the mains. As compared

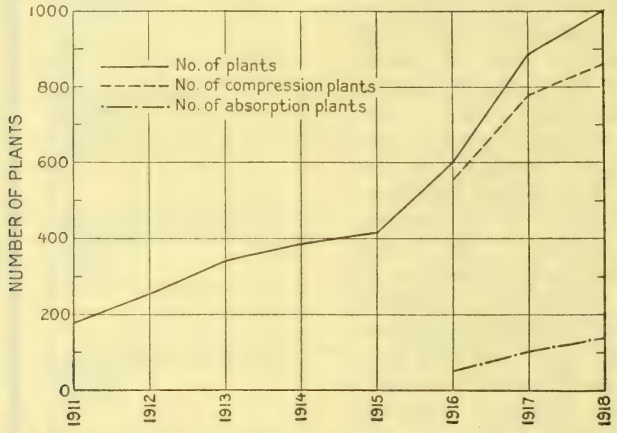

FIGURE 121.—Number of plants producing natural-gas gasoline in the United States, 1911–1918.

with the output by absorption in 1917, there was a gain in 1918 of 13,750,794 gallons, or 28.1 per cent. The average daily production of natural-gas gasoline in 1918 was 774,070 gallons.

The total output of gasoline in the United States in 1918 was 3,749,892,317 gallons.[2] Of this total output 3,467,356,767 gallons, or 92.5 per cent, was manufactured from crude petroleum by distillation, and the remaining 282,535,550 gallons, or 7.5 per cent, was natural-gas gasoline.

The outstanding feature of the industry in 1918 was the large increase in production by the compression plants in Oklahoma. Although the increase in output in Kansas in 1918 was 103 per cent, as compared with an increase of 42.2 per cent in Oklahoma, the contribution made by Oklahoma to the total output of natural-gas gasoline in the United States in 1918 was 48,577,126 gallons more than in 1917, whereas Kansas increased the total supply by only 1,214,876 gallons more than in 1917.

Of the 13 States engaged in the industry, 9 showed increases in production and 3 showed decreases. Wyoming made its first

[2] From statistics compiled by Bureau of Mines.

production in 1918. The States which increased their output during the year, listed in the order of percentage of increase, were as follows: Kansas, 103 per cent; Oklahoma, 42.2 per cent; Louisiana, 41 per cent; New York, 40.8 per cent; Ohio, 24 per cent; West Virginia, 15.1 per cent; Pennsylvania, 14.1 per cent; California, 12 per cent; and Texas, 5.9 per cent. The States which decreased their output are Colorado, 90.6 per cent; Kentucky, 12.8 per cent; and Illinois, 7.3 per cent.

In 1917 Ohio held sixth place and Louisiana held seventh place, but in 1918 the places of the two States were reversed.

The quantity of commercial gasoline produced in 1918 by blending the raw gasoline with distillates was 262,611,267 gallons, and the value was $52,163,133.

The estimated market value of the output of raw gasoline in 1918 was $50,363,535, an increase over the value in 1917 of $10,174,579, or 25.3 per cent. In 1918 the value of the product of the compression plants was $37,644,649, or 74.7 per cent of the total market value, and the value of the product of the absorption plants and of the drip from the mains was $12,718,886, or 25.3 per cent of the total. The average price received for the unblended gasoline at the sources of production in 1917 was 18.45 cents a gallon; in 1918 the average price dropped to 17.8 cents a gallon, a decrease of 3.4 per cent. The average selling price of the raw gasoline produced at the compression plants in 1918 was 17.1 cents a gallon—a decrease of 1 cent a gallon, or 5.5 per cent—and that of the raw gasoline recovered at the absorption plants and from the mains as drip was 20.3 cents a gallon—a gain of 0.69 cent, or 3.5 per cent.

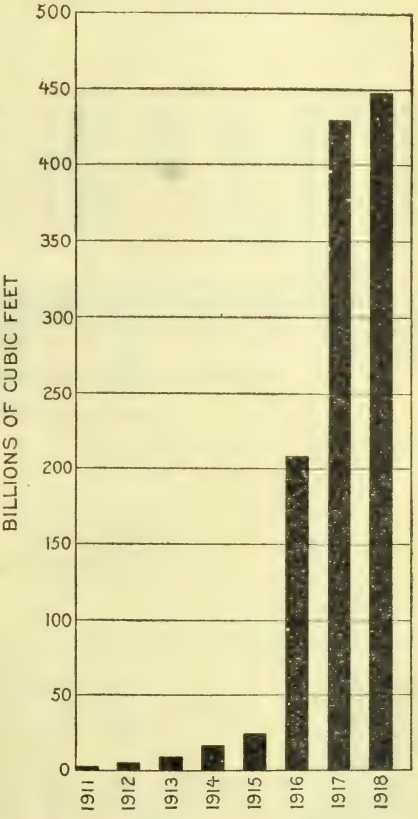

FIGURE 122.—Estimated volume of natural gas treated in the manufacture of natural-gas gasoline, 1911–1918.

The raw natural-gas gasoline produced in the United States in 1918 was extracted from about 449,108,661,000 cubic feet of gas, an increase in the volume of gas treated of 4.6 per cent, as compared with that in 1917 (fig. 122).

The total number of plants producing natural-gas gasoline in 1918 was 1,004, an increase of 118, or 13.3 per cent, over the number in 1917 (fig. 121).

In 1918 natural-gas gasoline was made in the United States by 503 operators.

STATISTICS OF NATURAL-GAS GASOLINE.

[a] Estimated.

[b] This number is irrespective of the kind, number, and location of the plants operated. The sum of the number of operators listed for each method employed and for each county and State will therefore not give the correct number of operators in the United States. A comparison of the number of operators in 1918 with the number in prior years can not be made because they have not been listed in the same way for those years.

United States, 1918	[a] 503	1,004	282,535,550	50,363,535	17.8	449,108,661	.63
United States, 1917	750	886	217,884 104	40,188,956	18.45	429,287,797	.508

[a] This number is irrespective of the kind, number, and location of the plants operated. The sum of the number of operators listed for each method employed and for each county and State will therefore not give the correct number of operators in the United States. A comparison of the number of operators in 1918 with the number in prior years can not be made because they have not been listed in the same way for those years.

NATURAL-GAS GASOLINE INDUSTRY, BY STATES.

CALIFORNIA.

California retained its place as third in rank among the States producing natural-gas gasoline in 1918; the output amounted to 32,268,933 gallons, valued at $5,009,152. This was the greatest production ever credited to the State in any one year, the increase over 1917 being 3,451,329 gallons, or 12 per cent. The output for the State was 11.4 per cent of the total for the United States.

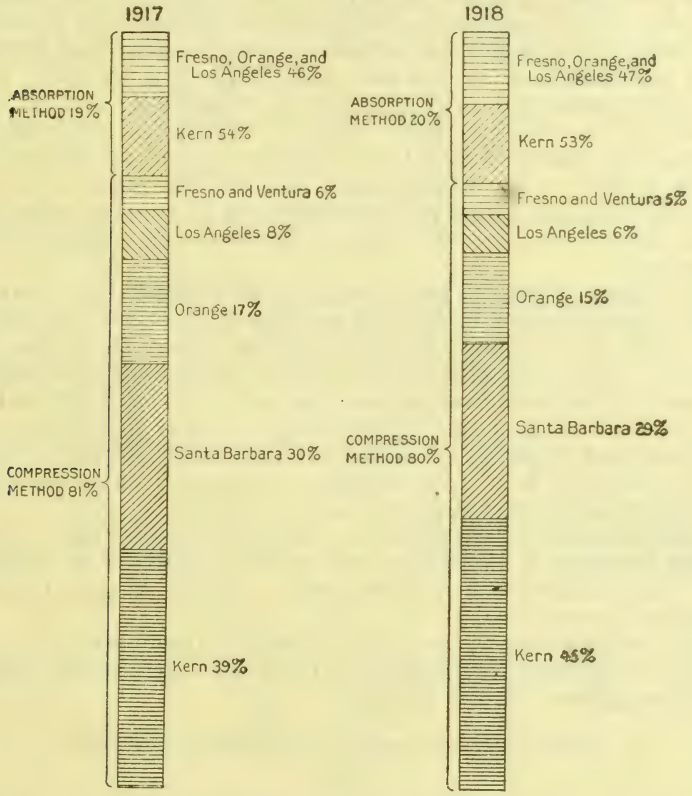

FIGURE 124.—Natural-gas gasoline produced in California in 1917 and 1918, by principal methods of manufacture and by counties.

Of the total quantity of gasoline produced in the State in 1918, 25,767,346 gallons, or 80 per cent, was produced by the compression method and 6,501,587 gallons, or 20 per cent, by the absorption process. The counties producing the gasoline by the compression method were Kern, 45 per cent; Santa Barbara, 29 per cent; Orange, 15 per cent; Los Angeles, 6 per cent; and Ventura and Fresno, 5 per cent. Only four counties have absorption plants; Kern ranked first with 53 per cent, and Los Angeles, Fresno, and Orange produced 47 per cent. There was an increase in production by both methods over 1917. California ranked second in the quantity of gasoline produced by the compression method, producing 11.7 per cent of

the total compression product in the United States in 1918, and fourth in the quantity of gasoline extracted at the absorption plants and obtained as drip from the mains, its output being 10.4 per cent of the total absorption product in the United States.

The average daily output of natural-gas gasoline in California in 1918 was 88,408 gallons, an increase of 9,456 gallons as compared with 1917. The quantity of commercial gasoline produced from the blending of the raw gasoline recovered from natural gas in California in 1918 probably amounted to 2,464,812 gallons, valued at $447,962.

The market value at the sources of production of the total output of raw gasoline in California in 1918 was $5,009,152, an increase of $571,130, or 12.9 per cent, as compared with the value in 1917. Of this combined value the compression product contributed $3,906,355, which was $268,528, or 7.4 per cent, more than in 1917; and the absorption plant and drip gasoline contributed $1,102,797, a gain of $302,602, or 37.8 per cent. The average price received for the raw gasoline produced was 15.5 cents per gallon, an increase of 0.1 cent over 1917. The compression gasoline averaged 15.2 cents a gallon and the absorption product averaged 17 cents a gallon, which, compared with 1917, show a loss of 0.3 cent and a gain of 2 cents, respectively.

The volume of natural gas treated in the extraction of natural-gas gasoline in California in 1918 is estimated at 50,490,019,000 cubic feet, which was 5,138,772,000 cubic feet more than the volume treated in 1917. Of this total volume, 33,162,732,000 cubic feet was used in the compression process and 17,327,287,000 cubic feet in the absorption process. The average yield of gasoline per thousand cubic feet of gas was 0.64 gallon; the average yield for the compression product was 0.78 gallon per thousand cubic feet and for the absorption product 0.38 gallon.

At the end of 1918, 29 operators were engaged in the natural-gas gasoline industry in California and used 56 plants, 7 of which were new. The compression process was used in 39 plants and the absorption process in 17.

The accompanying diagram (fig. 124) and the following statistical tables show in detail the progress of the natural-gas gasoline industry in California from 1916 to 1918.

Natural-gas gasoline produced in California, 1916–1918.

[a] This number is irrespective of the kind, number, and location of the plants operated. The sum of the number of operators listed for each method employed and for each county will therefore not give the correct number of operators in the State. A comparison with the number of operators for prior years can not be made because thay have not been listed in the same way.

[b] Average.

[c] Includes drip gasoline.

COLORADO.

The 2,475 gallons of natural-gas gasoline produced in Colorado in 1918 was obtained from 1 compression plant in Boulder County. The total value of this output was about $620. The gas used was the casing-head gas from oil wells in the old Boulder oil field.

ILLINOIS.

Illinois experienced a decline in the natural-gas gasoline industry in 1918, the production decreasing 359,444 gallons, or 7.3 per cent, as compared with 1917. The total output for 1918 was 4,574,565 gallons, or 1.6 per cent of the total production in the United States. The average daily production in the State in 1918 was 12,533 gallons.

The market value of the gasoline sold was $890,436, an increase of $24,403, or 2.8 per cent, over the value in 1917, and the average price received at the point of production was 19.5 cents a gallon.

The total quantity of gas treated for gasoline extraction in 1918 was 2,316,646,000 cubic feet, or 369,249,000 cubic feet less than in the preceding year. The average yield of gasoline per thousand cubic feet of gas in 1918 was 1.97 gallons. The total quantity of commercial gasoline produced as a result of blending at the plants aggregated 1,540,516 gallons, with a market value of $247,290.

The natural-gas gasoline industry in Illinois is in Lawrence, Crawford, and Clark counties, in the eastern part of the State. The gas treated for the manufacture of gasoline was casing-head gas from oil wells, and the gasoline was extracted chiefly by the compression process. The exhaust gas was utilized mostly on the leases for pumping and drilling, and only a small proportion was sent through the pipe lines for distribution.

In 1918 there were 34 operators engaged in the natural-gas gasoline industry in Illinois. During the year 17 plants were completed, compared with 23 plants in 1917. There were 72 plants in operation, compared with 55 plants in 1917.

Natural-gas gasoline produced in Illinois, 1916–1918.

KANSAS.

Kansas showed an increase of 103 per cent in the production of natural-gas gasoline in 1918, as compared with a gain of 447 per cent in 1917. The total production in the State amounted to 2,389,856 gallons, of which 802,773 gallons, or 33.6 per cent, was produced by compression and vacuum-pump methods and 1,587,083 gallons, or 66.4 per cent, by absorption method and drip. The compression product was 0.36 per cent of the total quantity of gasoline produced by such plants in the United States in 1918, and the absorption process and drip supplied 2.5 per cent of the total output from these sources in the United States in 1918. The combined production in the State was 0.8 per cent of the total output in the United States. The average daily production in 1918 was 6,548 gallons.

The total market value of the raw gasoline in the State in 1918 was $593,730, of which $200,693 was attributed to the compression gasoline and $393,037 to the absorption and drip product. The gain in the total value in 1918 was $352,511. The average price increased from 20.53 cents to 24.8 cents a gallon in 1918.

Because of its high gravity test some of the raw gasoline was blended at the plants, and as a result 3,134,509 gallons of commercial gasoline, valued at $678,970, was produced.

The total quantity of gas consumed in the manufacture of gasoline in the State in 1918 was estimated at 16,023,067,000 cubic feet, an increase of 6,707,728 cubic feet over 1917.

The average yield of gasoline per thousand cubic feet of the gas utilized in 1918 was approximately 0.15 gallon, or a little more than the average yield in 1917. The gas, after the extraction of the gasoline, was either returned to the lessees or sold for domestic and industrial consumption.

At the end of 1918 there were 11 gasoline plants in operation in Kansas, of which 6 were compression plants and 5 were absorption plants, which were distributed through Butler, Chautauqua, Cowley, Montgomery, and Wilson counties. There were 5 operators engaged in the industry.

KENTUCKY.

Although the total production of natural-gas gasoline in Kentucky in 1918 was 3,330,986 gallons, 487,223 gallons less than in 1917, or a loss of 12.8 per cent, the State retained ninth rank among the producing States. The absorption plants produced 3,234,673 gallons and the compression plants 96,313 gallons. The product of the absorption plants and the drip gasoline constituted 5.2 per cent of the output of gasoline from these sources in the United States in 1918, and the output of the compression plants amounted to 0.04 per cent of the total. The combined output for Kentucky in 1918 was 1.2 per cent of the total production in the United States in that year. The average daily production in 1918 was 9,126 gallons.

It is estimated that 3,600,027 gallons of commercial gasoline, having an estimated value of $722,585, was produced by blending the raw gasoline in the State in 1918.

The average price received for the raw gasoline at the source of production in 1918 was 19.8 cents a gallon, and the market value of the entire output in the State was $660,108, a loss of 0.2 cent in average unit selling price and of $103,078, or 13.5 per cent, in total market value, as compared with 1917. The absorption gasoline, including the drip gasoline, was valued at $646,973, and the gasoline obtained at the compression plants at $13,135.

The volume of natural gas utilized in the extraction of the raw gasoline by the combined methods in 1918 was 19,816,518,000 cubic

feet. The absorption process consumed 19,768,711,000 cubic feet, or 99.8 per cent of all the gas used, and the compression method consumed 47,807,000 cubic feet. The natural gas was either produced by the operators themselves or purchased and, after the extraction of the gasoline, was used on the leases, sold to distributing companies, or forced back into the wells.

Six plants produced raw gasoline in the State in 1918, of which 4 were compression plants and 2 were absorption plants. The compression plants are in Morgan and Wayne counties and the absorption plants in Boyd and Martin counties. A small quantity of drip gasoline was recovered in Menifee County. The plants in 1918 were run by 5 operators.

LOUISIANA.

A production of 7,020,538 gallons of raw gasoline in 1918, a gain of 2,040,784 gallons, or 41 per cent, over the production in 1917, enabled Louisiana to move from seventh to sixth place among the States producing natural-gas gasoline. This output was 2.5 per cent of the total production in the United States. The compression plants contributed 5,903,723 gallons, or 84 per cent of the output, an increase of 32.4 per cent over the like product in 1917, and 2.7 per cent of the total gasoline produced in such plants in the United States in 1918. The remaining 1,116,815 gallons, or 16 per cent of the output of the State in 1918, was produced by the absorption process and the drips from gas mains and was an increase of 115 per cent over the quantity similarly produced in 1917, and 1.8 per cent of the

total output from these sources in the country in 1918. The average daily output of raw gasoline in Louisiana during 1918 was 19,234 gallons.

In the extraction of the gasoline 1,906,837,000 cubic feet of gas was treated at the compression plants and 11,555,480,000 cubic feet at the absorption plants, a total of 13,462,317,000 cubic feet for the year, which was a gain of 503 per cent over the quantity treated in 1917. The average recovery of gasoline per thousand cubic feet was 0.52 gallon by all methods, 3.1 gallons by the compression method, and 0.1 gallon by the absorption process and drip.

The total market value of the gasoline output for the State in 1918 amounted to $1,178,651, an increase of 44.7 per cent, as compared with 1917. Of this value, $847,509 was credited to the gasoline extracted by the compression method and $331,142 to that produced by the absorption method and salvaged as drip from gas mains. Compression gasoline showed an increase of 17.7 per cent and absorption gasoline of 249 per cent over the values for the gasoline produced by these respective processes in 1917. The average price received during 1918 for the raw gasoline at the sources of production was 16.8 cents a gallon, for the compression product 14.4 cents, and for the absorption and drip products 29.7 cents a gallon.

The quantity of commercial gasoline obtained by blending the raw gasoline was estimated at 1,161,685 gallons, valued at $194,564.

The quantity of gasoline reported to the Geological Survey was the product of 15 compression plants and 3 absorption plants, 2 less than the 20 plants operating in 1917. The compression plants are in Caddo and De Soto parishes, and the absorption plants in Caddo Parish alone. There were 9 operators engaged in the gasoline industry in 1918.

NEW YORK.

New York produced 218,131 gallons of natural-gas gasoline in 1918. Of this total output 211,131 gallons was produced by the compression method, and the remaining 7,000 gallons was salvaged from gas mains as drip gasoline. The average daily production was 598 gallons.

It is estimated that in New York 592,000 gallons of commercial gasoline, valued at $75,529, was obtained as a result of blending the raw gasoline.

The value of the total output of raw gasoline in New York in 1918 was estimated at $55,405, which was an average price of 25.4 cents a gallon.

The volume of natural gas treated, as far as can be ascertained, was probably 99,487,000 cubic feet, and the average yield of raw gasoline per thousand cubic feet of gas was 2.19 gallons.

The total output was obtained from three compression plants and from gasoline salvaged as drip from transmission lines. The operations were conducted by four operators.

OHIO.

Ohio produced 6,744,907 gallons of natural-gas gasoline in 1918, 1,305,347 gallons more than in 1917, or an increase of 24 per cent. The State dropped from sixth to seventh place in 1918. Compression plants contributed 2,035,406 gallons, or 30.2 per cent of the State's output, and absorption plants 4,709,501 gallons, or 69.8 per cent. Ohio contributed 0.93 per cent of all the compression gasoline recovered in the United States in 1918 and 7.5 per cent of all the gasoline produced by the absorption method and salvaged as drip. The total State output was 2.4 per cent of the total quantity of natural-gas gasoline produced in the United States in 1918.

The average daily production in Ohio in 1918 was 18,479 gallons, as compared with 14,903 gallons in 1917. The quantity of commercial gasoline produced from the raw gasoline in 1918 was approximately 1,611,739 gallons, having an estimated value of $358,788.

The average price received for the gasoline in 1918 was 20.1 cents a gallon, a rise of 0.77 cent a gallon over the price received in 1917. The average price for the compression-plant product was 19.4 cents a gallon, an increase of 1.29 cents; the average price for the absorp-

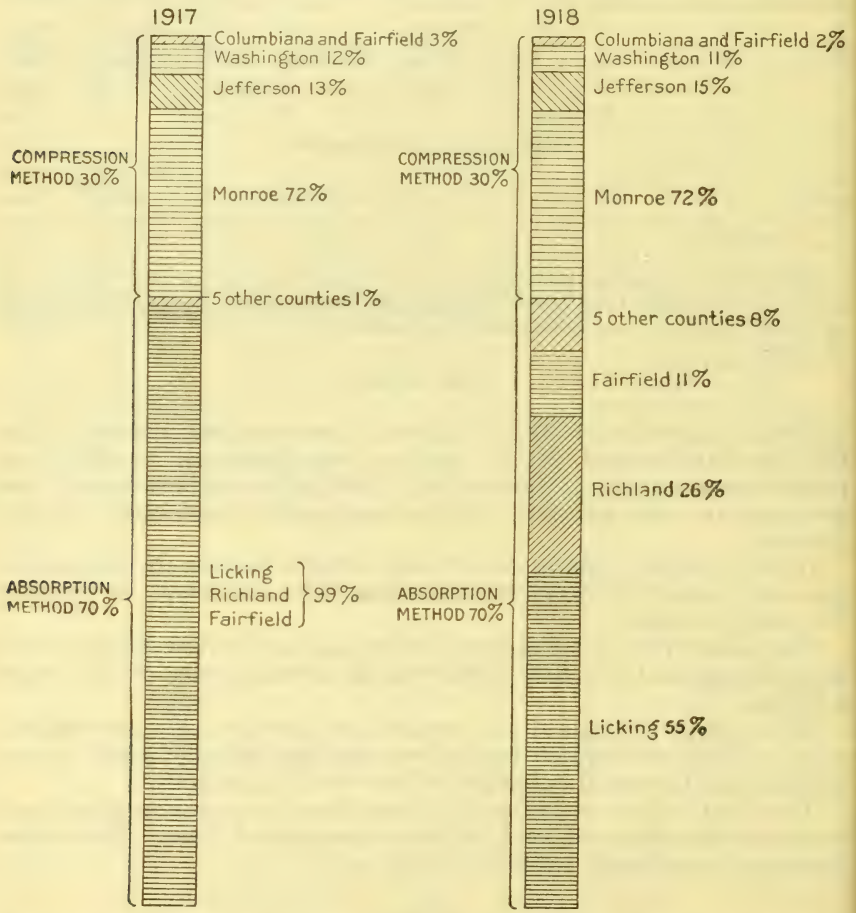

FIGURE 125.—Natural-gas gasoline produced in Ohio in 1917 and 1918, by principal methods of manufacture and by counties.

tion output and that derived from mains as drip was 20.4 cents a gallon, practically the same as in 1917.

The gasoline produced in 1918 was extracted from an estimated volume of 37,739,322,000 cubic feet of natural gas, with an average recovery of 0.18 gallon per thousand cubic feet. The average recovery of the compression gasoline was 2.87 gallons, and that of the absorption gasoline was 0.13 gallon.

During 1917 61 plants contributed to the gasoline production in Ohio, whereas in 1918, 55 were in operation—a decrease of about 10

per cent. Of the 55 plants 45 were of the compression type and 10 were of the absorption type. The compression plants were in Columbiana, Fairfield, Jefferson, Monroe, and Washington counties; the absorption and drip gasoline came from Fairfield, Knox, Licking, Lorain, Monroe, Noble, Richland, and Washington counties.

The output in Ohio was produced by 36 operators, 28 of whom operated compression plants and 8 operated absorption plants and contributed drip gasoline.

The accompanying diagram (fig. 125) and the following tables show in detail the production of natural-gas gasoline in the State from 1916 to 1918.

Natural-gas gasoline produced in Ohio, 1916–1918.

[a] This number is irrespective of the kind, number, and location of the plants operated. The sum of the number of operators listed for each method employed and for each county will therefore not give the correct number of operators in the State. A comparison with the number of operators for prior years can not be made because they have not been listed in the same way.

[b] Average.

[c] Includes drip gasoline.

OKLAHOMA.

The growth of the natural-gas gasoline industry in Oklahoma has been remarkable. From fourth in rank in 1911, Oklahoma advanced in 1914 to first place, which it has occupied for the last five years. The diagram (fig. 119) shows this rise in relation to the other States producing natural-gas gasoline.

In 1918 Oklahoma contributed 57.9 per cent of the total production in the United States, with an output of 163,700,550 gallons of raw gasoline. This quantity was an increase of 48,577,126 gallons, or 42.2 per cent, over the production in 1917. The quantity of raw gasoline received from the compression plants was 154,271,605 gallons, or 41.9 per cent greater than in 1917, and 94.2 per cent of the combined production for the State; the quantity recovered by absorption, including drip, was 9,428,945 gallons, 5.8 per cent of the total State production and 47.4 per cent more than the product by that method in 1917. Oklahoma contributed 70.2 per cent of the compression-plant gasoline produced in the United States in 1918, and 15 per cent of the total absorption-plant gasoline. The average daily production in 1918 was 448,495 gallons.

The quantity of commercial gasoline produced by blending the raw gasoline extracted from natural gas in Oklahoma in 1918 was 215,857,434 gallons, having an estimated value of $43,194,180. This production was greater than in any other State by a margin of 201,514,313 gallons over West Virginia, the nearest competitor.

The market value of the entire output of raw gasoline in Oklahoma in 1918 was $28,389,045, a gain of 31.8 per cent over the value in 1917. The average price received at the source of production for all the gasoline in 1918 was 17.3 cents a gallon, which was a decrease of 1.41 cents as compared with the average price of 18.71 cents in 1917. The average selling price for the compression-plant product in Oklahoma in 1918 was 17.2 cents a gallon, a decrease of 1.5 cents as compared with 1917; the absorption product sold in 1918 for 19.8 cents a gallon, an increase of 0.72 cent over the price in 1917. The value of the raw compression gasoline in Oklahoma in 1918 was $26,521,398, and that of the absorption gasoline, including drip, was $1,867,647.

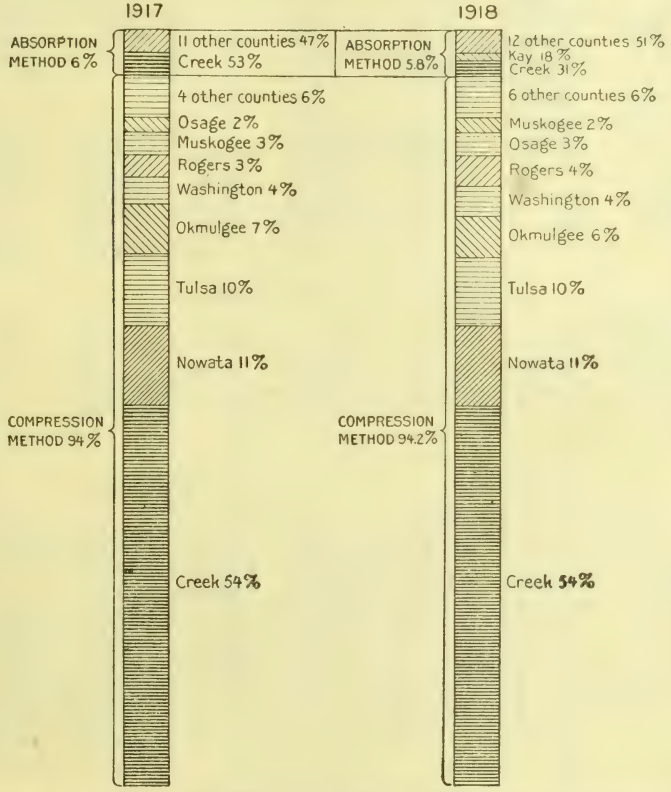

FIGURE 126.—Natural-gas gasoline produced in Oklahoma in 1917 and 1918, by principal methods of manufacture and by counties.

The gasoline produced was obtained from 78,322,307,000 cubic feet of natural gas, which was 6,397,634,000 cubic feet, or 7.6 per cent, less than the volume utilized in 1917. The compression plants used 46,684,983,000 cubic feet, and the absorption plants the remaining 31,637,324,000 cubic feet. The average yield of raw gasoline per thousand cubic feet for the entire output was 2.09 gallons; the compression product yielded 3.30 gallons and the absorption product 0.30 gallon, which was an increase over the yield in 1917 in both types.

The construction of new plants during 1918 resulted in the operation of 276 plants as compared with 234 in 1917, a gain of 42 plants, or 17.9 per cent. The compression plants numbered 238 in 1918, 31

more than in 1917; the number of absorption plants in 1918 was 38, as compared with 27 in 1917.

Compression plants were run by 116 operators and absorption plants by 20 operators in 1918.

The accompanying diagram (fig. 126) and the following tables show in detail the production of natural-gas gasoline in Oklahoma from 1916 to 1918.

PENNSYLVANIA.

For the fifth consecutive year Pennsylvania in 1918 held fourth rank among the States producing natural-gas gasoline. Its production of 15,775,058 gallons constituted 5.6 per cent of the total output of the country and was an increase of 14 per cent over 1917. It consisted of 9,158,795 gallons of raw gasoline recovered by the compression and vacuum-pump methods and 6,616,263 gallons supplied by absorption plants, including drip gasoline from the mains. This was a gain over the production in 1917 of 1.6 per cent in compression gasoline and of 37.4 per cent in absorption and drip gasoline. The production by the compression and vacuum-pump method was 58.1 per cent of the State production in 1918 and 4.2 per cent of the total production in the United States by these methods. The absorption

plants, including drip, produced 41.9 per cent of the State's output in 1918 and 10.5 per cent of the total absorption and drip gasoline recovered in the United States in 1918. The actual increase in the combined production in 1918 was 1,948,808 gallons, which resulted from an increased output of 147,596 gallons by the compression plants and 1,801,212 gallons by the absorption plants. The average daily production in the State in 1918 was 43,219 gallons.

The output of commercial gasoline in the State in 1918 was 9,873,707 gallons, obtained by blending the raw product with naphthas and various distillates. It has been estimated that this quantity had a value of $1,998,418.

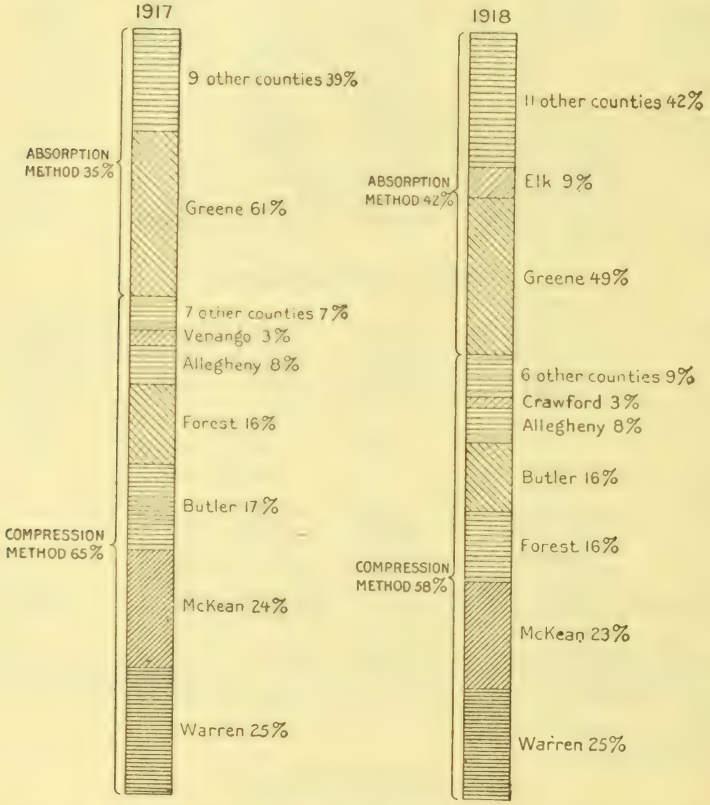

FIGURE 127.—Natural-gas gasoline produced in Pennsylvania in 1917 and 1918, by principal methods of manufacture and by counties.

The combined output was valued at $3,249,233 in 1918, a gain of $471,135, or 17 per cent, over 1917, and consisted of compression gasoline valued at $1,793,334 and absorption gasoline valued at $1,455,899. The values of gasoline produced by both processes increased over those in 1917. The raw gasoline obtained at the compression plants brought an average price in 1918 of 19.6 cents a gallon, which was slightly less than in 1917, whereas the absorption and drip gasoline increased in average price from 20.47 cents a gallon in 1917 to 22 cents a gallon in 1918, a gain of 7.5 per cent. The average selling price for the combined output in 1918 was 20.6 cents a gallon, or 2.9 per cent gain over the average price in 1917.

The gasoline was extracted from approximately 56,982,063,000 cubic feet of natural gas, making an average yield of 0.28 gallon of raw gasoline per thousand cubic feet of gas used, practically the same as in 1917. The average yield per thousand cubic feet at the compression plants was 2.33 gallons in 1918, a loss of 0.19 gallon, or 7.5 per cent, and at the absorption plants the yield was 0.12 gallon.

Pennsylvania outranks all other States in the total number of gasoline-extraction plants. In 1918 there were in operation 282 plants, an increase of 31 plants, or 12.35 per cent, over the number in operation in 1917. The compression plants numbered 259 in 1918, as compared with 234 in 1917, a gain of 10.7 per cent, and the absorption plants increased from 17 to 23, a gain of 35.3 per cent. The plants in operation in 1918 were distributed over 14 counties in the State, of which 12 contained compression plants and 13 absorption plants.

The combined output in 1918 was produced by 200 operators, of whom 192 conducted compression plants and 12 conducted absorption plants.

The accompanying diagram (fig. 127) and the following tables show in detail the natural-gas gasoline industry in Pennsylvania from 1916 to 1918.

[d] Drip gasoline only.

TEXAS.

Texas retained fifth rank among the States producing natural-gas gasoline in 1918, the output credited to the State being 7,326,122 gallons, which was 405,717 gallons, or 5.9 per cent, more than in 1917. This quantity constituted 2.6 per cent of the total output of natural-gas gasoline in the United States in 1918. The compression plants contributed 4,024,898 gallons of gasoline, which was 54.9 per cent of the combined output in the State, and the absorption plants, including drip, supplied 3,301,224 gallons, or 45.1 per cent. The compression gasoline was 1.8 per cent of the total compression and vacuum-pump production in the United States in 1918, and the

absorption gasoline, including drip, constituted 5.3 per cent of the total quantity of gasoline recovered by this method in the country in 1918. The average daily production of all plants in 1918 was 20,072 gallons.

The quantity of commercial gasoline produced by the blending of the raw gasoline with various distillates, at the plants or by the refiners, was estimated at about 5,912,665 gallons, valued at approximately $979,162.

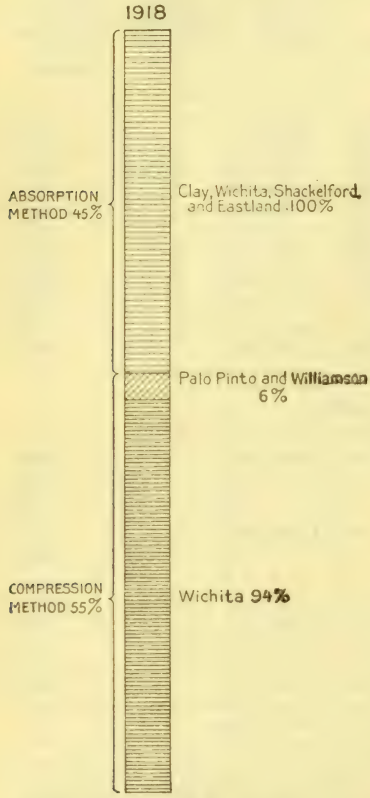

FIGURE 128.—Natural-gas gasoline produced in Texas in 1918, by principal methods of manufacture and by counties.

The market value of the total output of raw gasoline in 1918 was $1,214,565, an increase of 5.7 per cent over 1917. The compression-plant and vacuum-pump product was valued at $618,941, and the product of the absorption process, including drip gasoline, was valued at $595,624.

The average price received for the combined output of raw gasoline from both processes at the plants in 1918 was 16.6 cents a gallon, the same as that received in 1917.

The quantity of natural gas from which gasoline was recovered in 1918 was estimated at 8,493,182,000 cubic feet, 1,575,010,000 cubic feet being utilized by the compression method and 6,918,172,000 cubic feet by the absorption process. The average recovery of raw gasoline per thousand cubic feet by all methods was 0.86 gallon, or an increase of 0.31 gallon over 1917. The natural gas utilized in the manufacture of the raw gasoline was either produced by the operators themselves or purchased from other producers. The gas, after the extraction of the gasoline, was used for fuel directly on the leases or returned to the pipe lines for distribution.

The number of plants, of all types, recovering gasoline from natural gas, increased from 11 in 1917 to 13 in 1918. Returns on the production of gasoline were received from 9 compression plants and four absorption plants. The operators responsible for the output in 1918 numbered 8.

The accompanying diagram (fig. 128) and the following tables show the quantity of natural-gas gasoline produced in Texas from 1916 to 1918.

Natural-gas gasoline produced in Texas, 1916–1918.

WEST VIRGINIA.

West Virginia in 1918 remained second in rank for the third consecutive year among the States engaged in the natural-gas gasoline industry. Its production of 37,603,903 gallons was the State's largest output since the inception of the industry and was 13.3 per cent of the total production in the United States in 1918. This quantity surpassed the output in 1917 by 4,935,256 gallons, an increase of 15.1 per cent.

West Virginia ranked third among the States in the quantity of raw gasoline produced by the compression plants and vacuum pumps,

with 5.3 per cent of the total compression product in the United States. In the absorption-plant product, which in 1918 was 41.4 per cent of the total absorption gasoline produced in the United States, West Virginia leads all other States, exceeding Oklahoma, its nearest competitor, by 26.4 per cent. The total output at the compression plants in 1918 was 11,612,114 gallons, a decrease of 664,670 gallons, or 5.4 per cent, as compared with the output in 1917. The production at the absorption plants was 25,991,789 gallons, a gain of

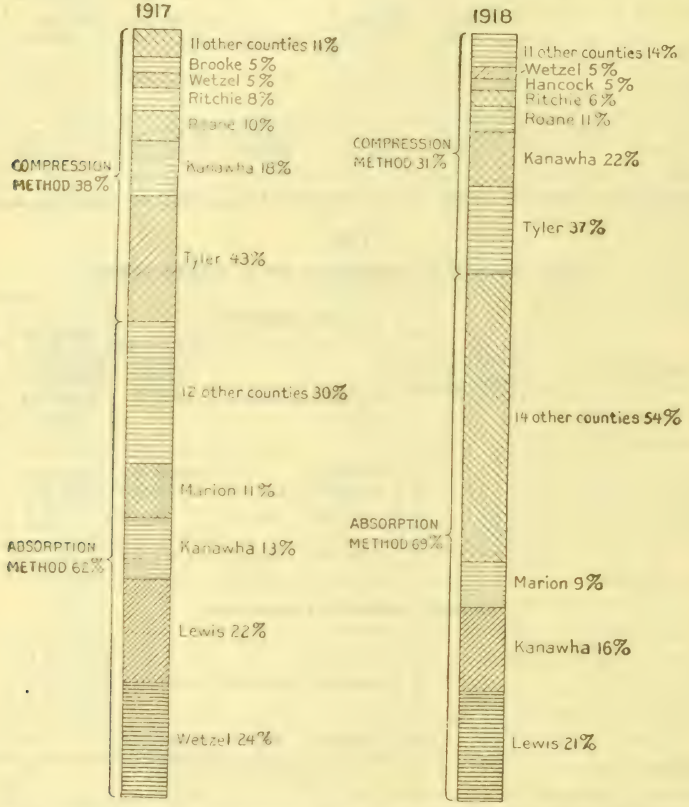

FIGURE 129.—Natural gas gasoline produced in West Virginia in 1917 and 1918, by principal methods of manufacture and by counties.

5,599,926 gallons, or 27.5 per cent. This marked increase accounts for the State's record output in 1918. Absorption plants contributed 69.1 per cent and compression plants 30.9 per cent of the combined output in the State.

Approximately 14,343,121 gallons of commercial gasoline, valued at $2,858,279, was produced in the process of blending the raw gasoline. This was the second largest quantity of commercial gasoline produced in the United States in 1918.

The market value of the total output of raw gasoline amounted to $7,498,804, an increase of $986,991, or 15.2 per cent; of this combined value absorption gasoline contributed $5,307,437 and compression gasoline $2,191,367. The average price received during 1918 for

the State's product was 19.9 cents a gallon, practically the same as in 1917. The compression gasoline averaged 18.9 cents a gallon and the absorption gasoline 20.4 cents a gallon, a gain of 0.86 cent, or 4.8 per cent, over the average unit selling price for the compression gasoline in 1917 and a loss of 0.67 cent, or 3.2 per cent a gallon, as compared with the average price received for absorption gasoline in 1917.

The gasoline produced was extracted from approximately 163,929,550,000 cubic feet of natural gas, which, despite an increased production, was less, by 3,841,801,000 cubic feet, or 2.3 per cent, than the volume utilized in 1917. Of this volume, 96.8 per cent was used at the absorption plants and 3.2 per cent at the compression plants.

At the end of 1918 there were 208 gasoline plants in operation in West Virginia, of which 172 were compression plants and 36 absorption plants. Compared with 188 plants in 1917, including 159 compression plants and 29 absorption plants, this shows an increase of 10.6 per cent in the total number of plants, or a gain of 8.2 per cent in compression plants and of 24.1 per cent in absorption plants. The gasoline plants are located in 22 counties.

The activities of 79 operators were responsible for the record output in 1918.

The accompanying diagram (fig. 129) and the following tables show in detail the natural-gas gasoline industry in West Virginia from 1916 to 1918.

[a] This number is irrespective of the kind, number, and location of the plants operated. The sum of the number of operators listed for each method employed and for each county will therefore not give the correct number of operators in the State. A comparison with the number of operators for prior years can not be made because they have not been listed in the same way.

[b] Average.

[c] Includes drip gasoline.

WYOMING.

The construction of gasoline plants in Wyoming in 1917 resulted in the production of 1,579,526 gallons of raw gasoline in 1918, the first production made by that State. The value of the output was estimated at $268,339. The average price at the plants during 1918 was 17 cents a gallon.

It is estimated that 2,519,052 gallons of commercial gasoline, valued at $407,406, was produced in Wyoming in 1918.

COKE.

By C. E. Lesher and F. G. Tryon.[1]

INTRODUCTION.

The statistical work on coke conducted by the Geological Survey during the year 1918 was merged in the larger undertaking of the statistical division of the United States Fuel Administration. For the special statistics on coke collected during the war period the reader is referred to the report of the distribution division of the United States Fuel Administration, Part I of which, "The distribution of coal and coke," is a running account of the problems that faced the Fuel Administration in meeting the country's expanded requirements and of the measures taken to meet those problems. In Part III of the same report, "Statistical tables," will be found certain other data on coke. A list of references to tables and text concerning coke which are to be found in these reports is appended to this chapter. The present report will be practically confined to setting forth the results of the 1918 canvass of coke production conducted in customary fashion by the Geological Survey. The tables are given in a form to preserve the continuity of the records collected by the Survey since 1880. The report herewith thus consists of a skeleton only: for the flesh and blood of the story of how the coke industry was drafted into war service the reader is referred to the reports of the Fuel Administration mentioned above.

ACKNOWLEDGMENTS.

Without the hearty support of the producers of coke, thanks for which are cordially extended, the preparation of this report would have been impossible. To the railroads which supplied weekly or even daily information of cars of coke loaded acknowledgments are also due. The statistics were collected and compiled under the direction of the senior author; the text has been prepared by the junior author. Portions of the proof have been read by Mr. Howard N. Eavenson, for whose helpful suggestions many thanks are due.

UNIT OF MEASUREMENT.

The standard unit of measurement employed in the coke industry in the United States is the short or net ton of 2,000 pounds. Except where otherwise specified, this is the unit employed throughout this chapter.

REVIEW OF THE COKE INDUSTRY IN 1918.

For the coke industry, as for the mining of coal, the year 1918 was one of maximum production, the climax of the extraordinary

[1] The statistics in this report were collected and prepared by H. L. Bennit, of the United States Geological Survey, except those for imports and exports, which were compiled by J. A. Dorsey from records of the Bureau of Foreign and Domestic Commerce.

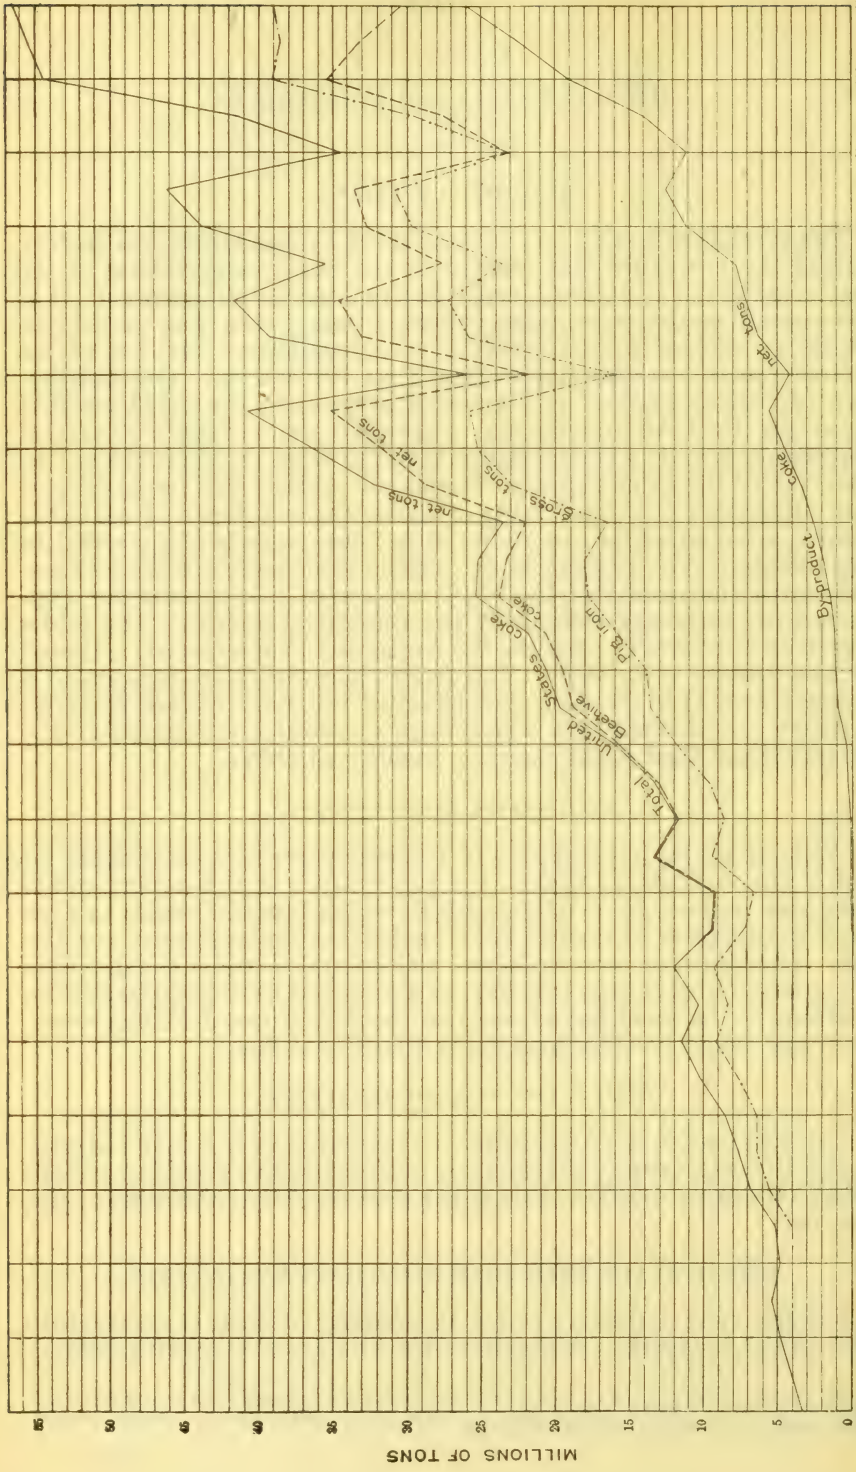

FIGURE 130.—Beehive and by-product coke and pig iron produced in the United States, 1880-1918.

industrial activity which marked in the United States the period of the World War. The record was the more remarkable in that it was achieved in spite of transportation difficulties associated with the tremendous burden laid by the war upon the railroads, and in spite of the unavoidable inroads of the draft upon the labor supply. The result was attained only by unstinted effort on the part of all concerned—operators, employees, railroads, and consumers.

The production in 1918 was 56,478,372 tons, an increase of 871,544 tons over that in 1917, which had hitherto been the record year. The output of the beehive coke decreased 8 per cent, but the decrease was more than offset by an increase of 16 per cent in by-product coke. In spite of the inroads of the retort oven, however, beehive ovens continued to furnish the greater part of the coke produced. As shown in the accompanying diagram (fig. 130) the lines of beehive and by-product coke production are rapidly converging and will probably cross each other at no distant date, but up to the end of the war the line of beehive coke remained clearly in the lead. In terms of percentage of the total the proportions in 1918 were beehive 54 per cent, by-product 46 per cent.

It is not difficult to marshal the principal events of 1918 in the history of the coke trade. They may be read at a glance in the accompanying diagrams of operating conditions, which tell the story, week by week, like the rings of growth in the stump of a tree. Operations in the Connellsville region, shown in figure 131, may be taken as typical of the beehive industry. The depression in January and February, 1918, when the weekly output was less than half of the rated capacity, reflects the breakdown of transportation attendant on the unprecedented storms of that winter. So low did the output of coke fall during this period, and so great were the delays in delivering coke already shipped, that many iron furnaces were forced to bank for lack of coke, the production of pig fell off 25 per cent (fig. 132), and the success of the war program was threatened. By the use of priority orders attempts were made to supply the most urgent needs, but little could be accomplished in that direction when practically every ton of metallurgical coke available was already contributing to the war program. Throughout the first quarter of the year transportation was the dominant factor limiting production, but about April 1 the untiring efforts of the railroads, assisted by the Government, began to bear fruit, and production was raised to 67 per cent of the rated capacity. The improvement in car supply disclosed a growing shortage of coke-oven labor, which remained the limiting factor from then to the end of the year. Transportation continued to improve until, beginning with May 12, the ovens were furnished with cars for all the coke they could load. From the middle of May to the middle of August the car supply continued perfect, and although occasional reports of car shortage were received thereafter, at no time did the transportation loss amount to more than 5 per cent. In the meantime the coke workers in the Connellsville region, responding loyally to appeals for increased production, labored so well as to make up for the inroads of the draft. Strikes were practically nonexistent. The increase in labor losses shown for November and December was due largely to the epidemic of influenza.

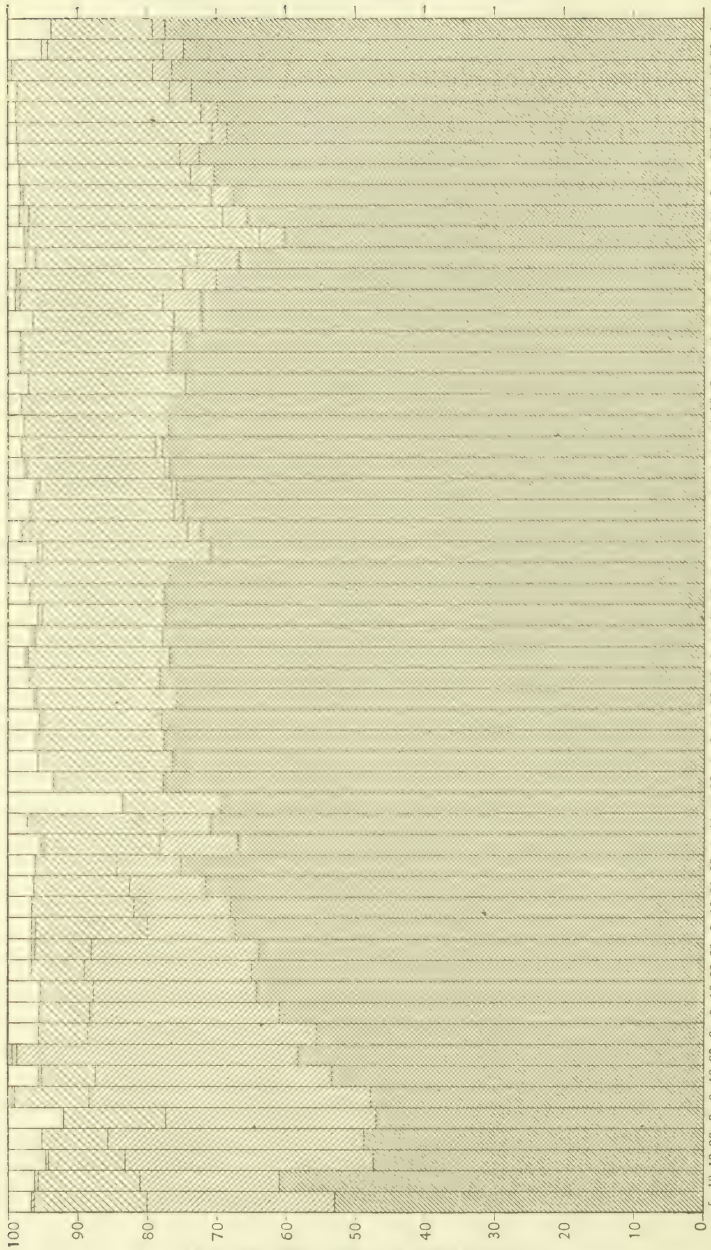

FIGURE 131.—Percentage of rated capacity produced and percentage "lost" from various causes in the Connellsville beehive-coke region, by weeks, January, 1918, to February 1, 1919.

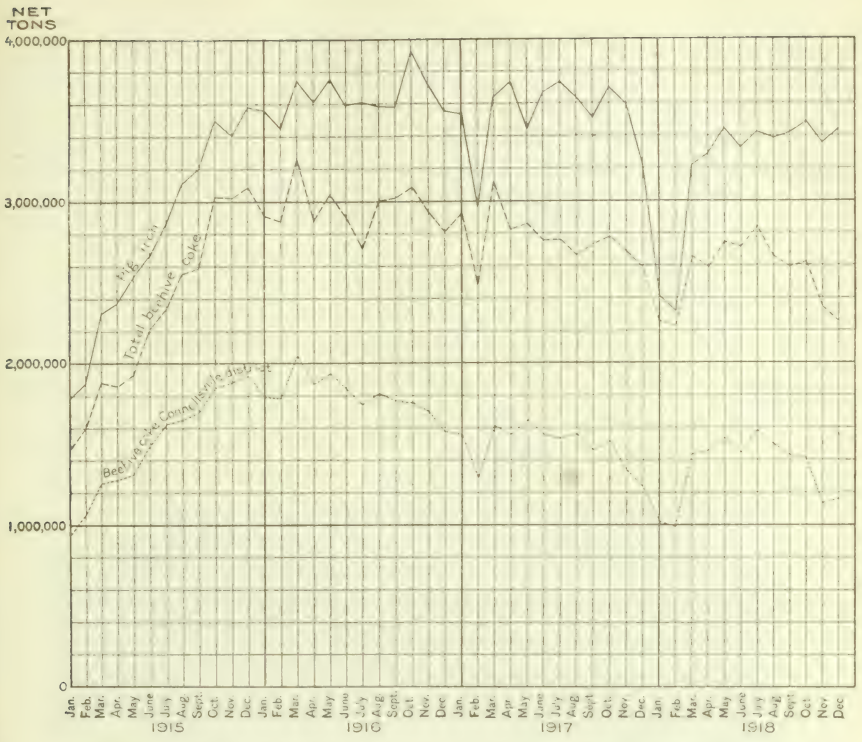

FIGURE 132.—Pig iron and beehive coke produced in the United States, by months, 1915–1918.

In the operation of the by-product plants also (fig. 133) transportation was the limiting factor early in 1918. Their difficulty was not lack of coke cars but delays in delivery of by-product coal. Stocks of high and low volatile coal at many by-product ovens in January fell to less than a week's supply. The week of minimum operation was January 13–19, when production fell to 67 per cent of capacity. The situation was especially critical because it involved a loss not only of coke but of the by-products needed for explosives. By the middle of March, however, improvement of transportation had so increased the reserves of coal on hand at the plants that an operation of 87 per cent was possible. By midsummer the limit of practicable operation, set by unavoidable breakdowns, had been reached and at this rate production was steadily maintained up to the time of the armistice, when a new factor—lack of demand—came into play. To make possible this maximum operation a reserve stock of by-product coal on hand at the plants sufficient to last five weeks was built up. In the meantime the construction of new by-product ovens was being pushed with all possible speed, and no month passed without material additions to the oven capacity of the country.

The success of the efforts to increase production may be judged from the fact that the output of all coke in October, 1918, was 5,169,000 tons, or at the rate of 62,000,000 tons a year.

On the day the armistice went into effect 718,000 tons of coke was on hand at blast furnaces, and out of 410 stacks only 2 were shut down for lack of coke.

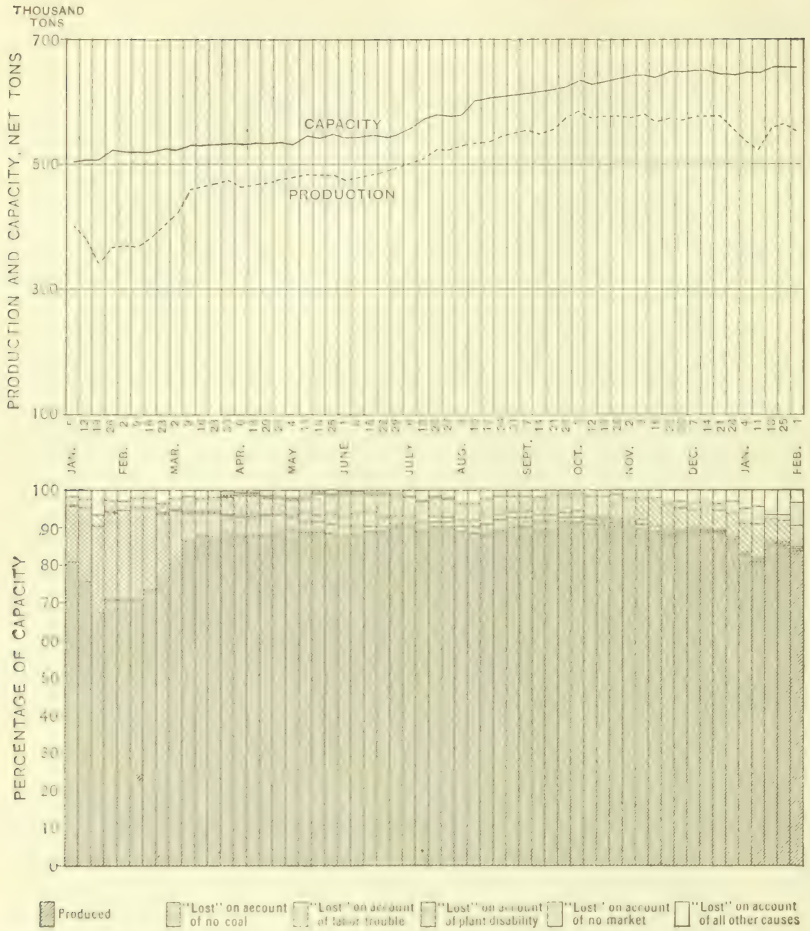

FIGURE 133.—By-product coke produced, maximum oven capacity, and operating conditions at the ovens, by weeks, January, 1918, to February 1, 1919.

During the year there was a decrease of 3,392, or 4 per cent, in the number of beehive ovens. By-product ovens, on the contrary, increased 1,410 in number and 25 per cent in capacity. New by-product plants were completed at Pueblo, Colo.; St. Paul, Minn.; Cleveland, Ironton, and Lorain, Ohio; and Clairton, Pa.; and additions to existing plants were made at Gary, Ind.; Sparrows Point, Md.; Youngstown, Ohio; Johnstown and Steelton, Pa.; and Chattanooga, Tenn. At the end of the year 1,815 other ovens were under construction.

Largely because of the unusual conditions surrounding the industry the average yield of coke from coal decreased. For beehive ovens it was 63.3 per cent; for by-product ovens 70.5 per cent.

The value of the products increased largely over that for 1917. Beehive coke at the ovens was valued at $189,000,000 and by-product coke at $193,000,000, a total of $382,000,000 for coke alone, as against $298,000,000 in 1917. The value of breeze and the several by-products brings the total for the industry as a whole in 1918 to $462,000,000.

An increase in the quantity of by-products produced more than offset the effect of decreased prices for benzol and toluol. Sales of by-products amounted to $75,000,000, an increase of $10,000,000, or 15 per cent, over the sales in 1917. Striking testimony to the contribution of the industry to the manufacture of munitions is seen in the fact that of the crude light oils, the chief source from which benzol, the base of picric acid, and toluol, the base of TNT, are derived, the by-product coke ovens contributed 78 per cent.

THE COKE-PRODUCING INDUSTRIES.

Coke is produced in the United States by a group of four industries which are related in the sense that the product is more or less interchangeable, but which are sharply differentiated as to location, methods, equipment, and organization. Besides that produced in the familiar beehive and by-product ovens, coke is obtained in the refining of petroleum and in the manufacture of coal gas.

The petroleum coke may be dismissed with a word. In refining crude oil the ultimate residue left in the stills is a porous, carbonaceous solid, which is broken up into chunks and thrown out. Its properties are much like those of coke made from coal, except that it is finer in texture and lacks the strength required for metallurgical coke. The best petroleum coke is extraordinarily low in ash, running less than 1 per cent—a quality which adapts it to the manufacture of carbon electrodes. For this purpose it brings a high price—during the war as much as $18 a ton. Petroleum coke that can not meet the specifications for electrode manufacture is commonly used as boiler fuel about the refinery. The total quantity of petroleum coke produced in 1914, according to the census of manufactures, was 213,777 tons, valued at $818,889, an average of $3.83 a ton. In 1917 the output, according to statistics collected by the United States Bureau of Mines, had risen to 539,366 net tons; in 1918 it was 559,663 tons.

In the coal-gas industry, as in petroleum refining, the coke obtained is a by-product. The process of carbonization is essentially the same as that in by-product ovens, though the type of oven is very different. The coals used are selected for their yield in gas rather than for their coking qualities, and the coke formed is too soft for furnace or foundry use. It is, however, well adapted to the manufacture of water gas, a fact which has led to the common association of coal-gas and water-gas plants as parts of the same city supply. Indeed, of the 3,180,535 tons of gas-house coke produced in 1918, 43 per cent was used in water-gas manufacture or for boiler fuel about the plant where it was produced. The remainder, 1,814,000 tons, was marketed, largely as domestic fuel, for a total of $14,022,818.

Neither petroleum coke nor gas-house coke is adapted for metallurgical purposes—the use which consumes over 90 per cent of all the coke produced. Practically speaking, therefore, the coke trade is concerned only with beehive and by-product coke, and to them the statistics in this report are confined. Although their product is interchangeable, there are fundamental differences between the beehive and by-product industries which must not be lost sight of in examining the tables of this chapter. The manufacture of beehive coke is essentially a small-unit industry; that of by-product coke is a large-unit industry.

In the beehive industry, the older of the two, the coal is charged into beehive-shaped or rectangular brick ovens of small capacity and burned with slight access to air, the heat required for coking being furnished by the combustion of the volatile matter and a part of the carbon. The beehive oven is well adapted to pioneering. It can be built in remote mining camps, wherever a seam of coking coal crops out, to supply an infant copper or iron industry. To avoid the cost of transportation on that part of the coal that is not converted into coke, the ovens are located at the mines. There is no recovery of by-products and no general market for the breeze or fines produced. The capital investment per oven is small, and the time required to construct an oven is brief. Each oven is a unit, and coke may be made on any scale, large or small. Although during the last 30 years there have been large consolidations of beehive operations, notably in the Connellsville district, the incentive to amalgamation was perhaps more the acquirement of reserves of coking coal than the unification of oven operation. The beehive oven is easily started up and as easily shut down. Deterioration from exposure to the elements is small and simply repaired. Producing coal of excellent quality for general use and therefore able to ship coal if not coke, the beehive operator is not confined to coke as his sole source of revenue. All these factors combine to make the overhead charges in beehive operation small and to adapt the industry to the fluctuating demand which has been a feature of American business.

In sharp contrast, the manufacture of by-product coke typifies large-scale modern industrialism. The by-product plant, with its intricately designed retort ovens, its use of power and machinery, its apparatus for by-product recovery, its tar and benzol stills, is essentially a chemical factory. It must be located near the point where the first among the by-products—the gas—is to be used, ordinarily near some large center of population. Not only are the volatile products in the gas recovered, but maximum efficiency in the utilization of fines and other wastes is possible. The by-product plant requires technical skill of the highest order, large initial investment, and large operating units. All these things mean heavy overhead expenses per ton of coke produced and put a premium on continuous operation.

The two industries have long been in competition. On the continent of Europe beehive coking went out of existence years ago, but in the United States it has persisted, although the good points of by-product ovens are as well known to the beehive operators as to anyone else. In fact, many of the active movers in by-product development have been financially allied with the companies that were producing beehive coke. Among the causes that have retarded the installation of retort ovens has been the small demand for many of the by-products in America. The ammonia could be easily marketed, but the lack of a dyestuffs industry in America meant small demand for the group of benzol products and low prices for tar. No less important was the absence of markets for gas near the chief centers of steel manufacture. In the Pittsburgh district by-product oven gas had to meet the competition of natural gas, which is superior in heating efficiency and for many years was available in unlimited quantity at exceedingly low prices. The very fact that the population is less dense in the United States than in Europe operated to discourage the

recovery of by-products here. Moreover, the violent fluctuations in the production of iron and steel and consequently in the demand for coke, more marked in the United States than in Europe, were less of a handicap to the beehive industry, with its low overhead charges, than to the by-product plants, where continuous operation was essential to profits. Not least among these forces has been the prodigality of the Nation's resources in fuel, which made it cheaper to mine more coal than to use efficiently that already mined.

In the equilibrium between beehive and by-product manufacture an influence of great potentiality is the relative freight rate on coke and on raw coal. The average ton of beehive coke represents only 70 per cent of the weight of the coal necessary to make the same coke in a by-product oven. Therefore, merely to equalize transportation costs, beehive coke can stand a considerable freight differential in excess of coal. In recognition of this fact rates on coke have generally been higher than those on coal. Any disturbance of existing differentials between coal and coke rates would tend to alter the terms of competition between beehive and by-product coke.

CHANGE IN FORM OF INQUIRY IN 1918.

Certain changes in the form of inquiry used by the Geological Survey in 1918, which affect the comparability of some of the figures for 1918 with those for earlier years, should be borne in mind in examining the tables of this report. Prior to 1918 it had been the practice of the Geological Survey to ascertain the total quantity of coke produced, whether sold or used by the producer. No separate statement of sales was obtained, but instead a statement of the value of the entire product, including an estimate of the value of coke used but not sold. This form of inquiry was well adapted to the beehive-coke industry where the proportion of the output used by the producer was small. Applied to the growing by-product coke industry, however, it gave less and less satisfactory results. In the manufacture of by-product coke the bulk of the product is utilized by the operator and any figure of total value is naturally a matter of conjecture.

To obviate this difficulty the schedule used in 1918 was altered so as to ask separately for the quantity produced, the quantity sold, and the value of the quantity sold. (See reprint of schedules, p. 1524.) Where a measure of the total value of the entire output was required it has been estimated by the Geological Survey by assigning to that part of the output used by the operator an average value corresponding to the average of the sales reported for the same locality.

Still other changes were made in the inquiries concerning by-products. These had formerly asked for the quantity and value of "by-products obtained and sold," a form which sometimes failed to elicit the total production. The 1918 schedule asked for production, sales, and values of sales separately, and the figures are therefore not all comparable with those for 1917.

The result of the new form of inquiry may be summarized as follows:

Beehive and by-product coke produced and sold in the United States in 1918.

	Beehive.	By-product.	Total.
Produced [a] tons	30,480,792	25,997,580	56,478,372
Sold:			
Furnace coke:			
Quantity tons	23,216,627	4,147,695	27,364,322
Value	$137,782,308	$30,792,247	$168,574,555
Foundry coke:			
Quantity tons	2,230,156	1,631,052	3,861,208
Value	$16,802,144	$15,849,017	$32,651,161
Domestic and other coke:			
Quantity tons	210,511	2,537,059	2,747,570
Value	$1,319,053	$18,907,079	$20,226,132
Total sales:			
Quantity tons	25,657,294	8,315,806	33,973,100
Value	$155,903,505	$65,548,343	$221,451,848
Used by producer tons	4,885,318	17,753,348	22,638,666
Estimated total value of coke produced [a]	$189,305,583	$193,018,785	$382,324,368

[a] Excluding breeze, of which 124,142 tons was produced at beehive coke plants and 1,999,370 tons at by-product plants, a total of 2,123,512 tons.

PRODUCTION.

SUMMARY.

The following tables summarize by States the principal facts concerning the beehive and by-product coke industries in 1917 and 1918. Certain of the States have only one or two producers, and returns from these operators are given in combinations in order not to disclose individual figures. Permission was requested and has been granted to publish as State totals the quantities reported for by-product coke in Colorado (1918 only), Kentucky, Maryland, Massachusetts, New Jersey, Tennessee, Washington, and West Virginia, and for beehive coke in Georgia and Ohio. Thanks are due to the officials of the companies in these States for this courtesy.

The total production of coke in 1918 was 56,478,372 tons, an increase over 1917 of 871,544 tons. The increase came entirely from by-product ovens, the output of which rose from 22,439,280 to 25,997,580 tons, a gain that more than counterbalanced a decline in the production from beehive ovens.

While the total output increased 1.6 per cent, the value—largely estimated—increased 28 per cent, rising from $298,000,000 to $382,000,000.

The summary table of production, by States (p. 1451), discloses clearly the localities in which the increase occurred. In terms of quantity Ohio led all other States, her increase amounting to 1,670,941 tons. In terms of percentage the greatest change was in New Jersey, where the construction of new by-product ovens late in 1917 was the cause of an increase of 61.1 per cent. Except in New Mexico, the output of beehive coke declined in every State, while that of by-product coke increased in all States but five—Alabama, Illinois, Kentucky, Maryland, and Massachusetts. Of the four States reporting an increase in total production of 200,000 tons or more—Ohio, Indiana, Minnesota, and New Jersey—all were outside the regions producing adequate quantities of coking coal. This is in accord with the tendency shown by the coke industry in recent years to migrate away from the mine, as by-product ovens located near the furnaces gradually replace beehive ovens at the mines.

Coke produced in beehive and by-product coke ovens in the United States, 1917–18.

BEEHIVE COKE.

The story of the beehive-coke industry during the last decade may be read from the following table of production, by States. From 1909 to 1917 the industry was virtually stationary. In the years of marked business activity it reached an annual output of 33 to 35 million tons; in dull years it dropped to 27 million tons, as in 1911 and 1915, or even to 23 million tons, as in 1914. The fluctuations in production during this period were more marked than those recorded in the by-product coke industry. The smaller capital investment per ton of output adapts the beehive industry to a position as an auxiliary source of coke supply, in contradistinction to the by-product industry, where heavy capital charges make steady operation essential.

The war demands for iron and steel called forth in 1916 a production of 35,464,000 tons of beehive coke, the maximum in the history of the industry. Thereafter competition of by-product ovens cut heavily into the output of beehive coke, which declined successively to 33,168,000 tons in 1917 and to 30,481,000 tons in 1918.

The most striking feature of the table is the position of dominance held by Pennsylvania in the beehive-coke industry. In the first year of the decade Pennsylvania produced 70 per cent of the total output; in the year of maximum production her proportion increased to 77 per cent, and even in 1918 it was 72.5 per cent of the total. If to the output of Pennsylvania is added that of the other States of the East, the dominance of the Appalachian region becomes even more apparent. The total production from the Western States in 1918 was 1,910,908 tons, or only 6.3 per cent of the total for the country.

Beehive coke produced in the United States in 1909–1918, in net tons.

[a] Included under "Combined States."

A characteristic tendency of the decade has been the abandonment of beehive coking in districts remote from the mines. Ten years ago beehive ovens were being operated in Illinois, Indiana, Montana, and Wisconsin, generally on coal brought in from the East. Their output was small, and they served a local market. The competition of by-product coke speedily forced these local operators to the wall. The year 1909 saw the last beehive coke produced in Indiana; in 1910 the industry dropped out in Montana and Illinois; in 1911 it disappeared in Wisconsin.

It was not alone in these outlying States that the competition of by-product ovens affected the output. New by-product plants producing in 1918 cut into the demand for beehive coke in several States, notably in Pennsylvania, Ohio, Alabama, and Colorado.

The estimates in the two following tables are based not on statements from the operators, but on current reports of railroad shipments. The method employed in making the estimates is explained on page 1507. The estimates published currently from month to month or week to week were later revised to agree with the total production as ascertained by the mine canvass at the end of the year.

Beehive coke produced in the United States, 1915–1918, by months, in net tons.

The causes limiting production in the Connellsville region, the country's greatest center of beehive coke, are analyzed in the following table, based on reports received weekly from representative producers. Each operator was asked to report the rating of his plant and to apportion the quantity "lost"—that is, the quantity by which his output fell short of his capacity—among different causes interfering with capacity production. The percentages shown in the following table are weighted averages of these individual reports. They show clearly the particular cause restraining production in the particular week. It would be misleading, however, to add the percentages together and obtain an average for the year, because each set of percentages is based on the conditions prevailing at the moment, conditions which depended in turn on the situation in the weeks preceding. Thus the fact that during the first quarter of 1918 little or no labor shortage was reported means only that labor shortage as a cause limiting output was obscured by the more important cause of car shortage. Later, when the car shortage was eliminated, the scarcity of labor was disclosed and thenceforth became the limiting factor.

Operating conditions in the beehive coke industry, as reported by representative operators in the Connellsville, Greensburg, and Latrobe districts, Pa.

Week ended—	Percentage produced.	Total "lost," all causes.	Percentage "lost" on account of—

BY-PRODUCT COKE.

SUMMARY.

Two tendencies are disclosed by the statistics of by-product coke production during the decade 1909–1918, shown in the following table. The first is the sharp rise in total production from 6,255,000 tons in 1909 to 25,998,000 tons in 1918, an increase of more than fourfold. In the first five years of the period the output doubled. In the next five years it doubled again.

No less significant, although less apparent, was the westward migration of the industry, toward the industrial centers of the Central States, with their demand for iron and steel products, and away from the fields that produce coking coal. In 1909 Pennsylvania was the largest producer, contributing 30 per cent of the output. At that time the by-product industry was already planted in the States to the north and east of the coal fields New England, New Jersey, New York, and Maryland—all of which were producing substantial quanties of by-product coke in 1909. Toward the West the industry was established in Illinois and Wisconsin and had made a small beginning in Ohio. Alabama reported a scant half million tons in 1909. During the next 10 years State after State in the West was added to the ranks of by-product producers. Production began in Indiana in 1910, in Washington in 1914, in Missouri in 1915, and in Colorado in 1918. A notable development in the Mahoning Valley and other districts in Ohio carried the production in that State from 83,000 tons in 1909 to 5,226,000 tons in 1918. This made Ohio the leading producer. The migration of the by-product industry toward the centers of consumption may be summed up in the statement that from 1909 to 1918 the production in States that contain deposits of by-product coal increased three and one-third times, while production in States that mine no by-product coal increased nearly five times.

By-product coke produced in the United States, 1909–1918, in net tons.

FACTORS LIMITING THE PRODUCTION OF BY-PRODUCT COKE.

The monthly production of by-product coke from January, 1917, to December, 1918, is shown in the accompanying table, based on current reports from the operators. The table shows the gradual increase in output attendant on the construction of new ovens. What it fails to bring out is the relation between production and capacity, a subject which is analyzed in the tables on pages 1459–1473. These tables are based on weekly reports from by-product plants made to the United States Fuel Administration and the Geological Survey. The reports were designed to enable the Fuel Administration to keep its finger on the pulse of the by-product industry as a source of the most necessary of war materials. So great was the demand for both coke and benzol products that maximum operation of all existing plants was a military necessity. The system of reports resembled that used in connection with beehive coke and bituminous coal. Each operator was requested to state the maximum weekly capacity of his plant and the coke produced and to apportion among specified causes the quantity of coke "lost." The records were essentially operating statistics, but they have historical value also. It is significant that even under the conditions of forced operation which prevailed in 1918 the by-product plants of the country seldom averaged more than 90 per cent of their maximum capacity, defined as the "maximum quantity of coke of the grade regarded as standard which can be produced with all ovens active when all conditions are favorable." It is difficult to imagine conditions more favorable than those existing late in the summer of 1918, yet the best performance attained in any one week was 92.2 per cent of capacity, recorded in the last week of September. The causes curtailing output in that week were plant disability, no coal, and labor trouble, to which losses of 4.7, 1.2, and 1 per cent, respectively, were attributed.

These data are of great significance in forecasting the quantity of coke that can be produced from a given equipment of ovens. They show clearly that under existing conditions in the United States an average operation of more than 90 per cent is exceptional, and that in calculating the capacity of the country's equipment of plants for either coke or by-products an average operation in excess of 90 per cent should not be assumed.[1]

By-product coke produced in the United States, 1917 and 1918, by months, in net tons.

Month.	1917	1918

SUBSTITUTION OF BY-PRODUCT FOR BEEHIVE COKE.

The story of the gradual replacement of beehive coke by coke made in by-product ovens may be read in the following table, which shows the percentage of the total quantity and value contributed by both types of ovens from 1880 to date. Since the installation of the first by-product ovens at Syracuse, N. Y., in 1893, when a total of 12,850 tons was produced, the rise of the by-product industry has been almost uninterrupted. Up to the beginning of the twentieth century, however, its progress was small, the output in 1900

amounting to only 5.2 per cent of the total production of coke. In 1905 it had risen to 10.7 per cent; in 1910 to 17.1 per cent; in 1913, the last year before the World War, to 27.5 per cent. Under the stimulus of the wartime demand for benzol and toluol rapid progress in the substitution of by-product coke for beehive coke was made. The beehive industry reached its maximum in 1916, with a total of 35,464,000 tons, or 65 per cent of the entire output. Thereafter the production of beehive coke steadily declined; from 1916 to 1918 it decreased nearly 5,000,000 tons, amounting in 1918 to 54 per cent of the entire output. In the meantime the production of by-product coke had increased amazingly, and in 1918 it constituted 46 per cent of the total.

The proportion of the value assignable to by-product coke was even larger—50.5 per cent in 1918. As the value is reckoned at the ovens, the price per ton of by-product coke contains an element which represents the cost of transporting the coal from the mine to the point of consumption and which is not included in the average price of beehive coke.

Coke produced in the United States, 1880–1918.

a Total in existence. No statistics available showing idle establishments.

RANK OF STATES IN PRODUCTION OF COKE.

The five leading producers of coke in 1918, in order of output, were Pennsylvania, Ohio, Alabama, Indiana, and West Virginia. The gradual encroachment of the by-product ovens has caused striking changes in the rank of individual States, even in the last five years. Pennsylvania has from the earliest times occupied first place as a producer of coke. Although her supremacy as the leading producer of all coke has not been challenged, in 1918 she lost first place as a producer of by-product coke to Ohio, which in 1914 occupied ninth place and in 1917 had risen to second place. Ohio has also forged rapidly upward in total production from eleventh place in 1914 to second place in 1918. Alabama, occupying in 1914 second place in point of total production and third place in output of by-product coke, fell in 1918 to third place in total output and fourth in by-product output.

Rank of the States in the production of coke, 1914–1918.

COKE IN PENNSYLVANIA.

Pennsylvania, though yielding to Ohio the first place in production of by-product coke in 1918, continued to be by far the largest producer in terms of all coke. The southward and westward extension of the iron industry, carrying with it the manufacture of both beehive and by-product coke, has, however, deprived Pennsylvania of the virtual monopoly she held in the early days. In 1880 the State produced 85 per cent of the country's total output. By 1900 the proportion had fallen to 65 per cent, in 1915 it was 62 per cent, and thereafter it steadily declined. As late as 1917 the State contributed one-half of the country's total supply of coke. In 1918, however, production in Pennsylvania declined both relatively and absolutely and constituted but 47.3 per cent of the total output of the country. These percentages taken by themselves fail to do

justice to the position of Pennsylvania in the coke industry, for in addition to her coke, she supplies much of the raw coal required by the by-product ovens in adjoining States.

The total production of all coke in Pennsylvania in 1918 amounted to 26,723,645 tons, a decrease as compared with the output in 1917 of 1,188,380 tons, or 4 per cent. There was an increase in the State's output of by-product coke, but it was more than offset by the decline in beehive coke. Under the stimulus of the high prices prevailing in 1918 the value of the product increased, rising from $135,698,000 in 1917 to $160,357,000 in 1918.

The quantity of beehive coke produced in 1918 is reported at 22,136,664 tons, a decrease from 1917 of 1,679,756 tons, or 7.1 per cent. Practically every district was affected by the decrease. Production in the Connellsville and Lower Connellsville districts is reported to the Geological Survey at 17,262,987 tons, or 78 per cent of the total of the State, about the same proportion as that contributed in 1917. Monthly shipments out of the Connellsville region, as recorded by the Connellsville Courier, are shown in the accompanying table. The number of beehive ovens also declined. In 1917 it had been 49,949; a year later it was 48,588, every district but one reporting a decrease. The average yield of coke from the coal charged in beehive ovens was practically the same—65 per cent, as against 65.1 per cent in 1917.

The construction of new retort ovens made possible an increase in the output of by-product coke, which amounted to 4,586,981 tons in 1918, an increase of 12 per cent over the output in 1917. Operations at the great Clairton plant of the Carnegie Steel Co. began in a preliminary way in June, 1918. Originally designed to include 640 Koppers ovens, the plant is to be enlarged by the construction of 128 additional ovens. This plant is the largest of its kind in the United States, if not in the world. Extensions at other existing plants were made at Johnstown and Steelton. The increase in output in 1918 was limited to the Pittsburgh district, which includes the Clairton plant. The output in that district amounted to 2,389,698 tons. The average yield of coke per ton of coal charged in by-product ovens declined from 71.6 to 70.4 per cent.

COKE IN WEST VIRGINIA.

The total output of coke in West Virginia declined slightly from 1917 to 1918, an increase of 18 per cent in the production of by-product coke being more than offset by a decline of 4.3 per cent in beehive coke. The total output of all coke is reported at 3,320,006 tons.

Beehive coke is produced in West Virginia in five distinct localities. Three of them—the Flat Top-Tug River district, the Kanawha district, and the New River district—are in the southern part of the State. The coal used is a low-volatile coal of excellent coking quality. The yields from the coal charged are small however, amounting to 58 or 59 per cent, as compared with the 67.6 per cent, for example, obtained in the Upper Potomac and Tygarts Valley fields, where the coal used is a high-volatile coal. It was in the Flat Top-Tug River district that the production of beehive coke decreased; in other districts a slight increase was reported.

The by-product coke plants of West Virginia lie in the Panhandle. There was no increase in number of ovens in operation in 1918, but 120 additional ovens were under construction at the end of the year. The total production was 603,393 tons, an increase of 92,360 tons as compared with the output in 1917.

Coke produced in West Virginia in 1917 and 1918.

COKE IN OHIO.

The State of Ohio has long been the center of a small beehive-coke industry but the production which amounted to 139,000 tons in 1918, is practically constant. It centers at Leetonia and other localitities, and the output is consumed locally.

The by-product coke industry in Ohio, however, has grown by leaps and bounds. The State has risen from ninth place as a producer of by-product coke in 1914 to first place in 1918. The change is in essence a migration from the mines of western Pennsylvania in the direction of the Lake front, at which shipments of ore coming down the Lakes are unloaded. The quantity of ore coming down the Lakes has been in excess of the quantity of coal moving up the Lakes, and the establishment of iron furnaces and coke ovens along the route from mine to Lake front, or even on the Lake front itself, has been in part the result of economic pressure to equalize these freight movements.

The total output of by-product coke in Ohio in 1918 was 5,226,334 tons, an increase over that of 1917 of 1,679,858 tons, or 47 per cent.

As shown in the accompanying table, there was an increase in each of the major producing districts, notably in the district outside of Canton, Cleveland, and Youngstown. New plants beginning operations in 1918 included the American Steel & Wire Co.'s plant at Cleveland, with 180 Koppers ovens, which began in April: the plant of the Ironton Solvay Coke Co. at Ironton, with 60 Semet-Solvay ovens; and the plant of the National Tube Co. at Lorain, with 208 Koppers ovens, both of which began in August. The Youngstown Sheet & Tube Co. added 102 new ovens to its existing battery of 204.

By-product coke produced in Ohio in 1916, 1917, and 1918.

COKE OVENS IN THE UNITED STATES.

INCREASE IN BY-PRODUCT OVENS.

The number of beehive ovens[1] in the United States has been decreasing for years, irrespective of the fluctuations in the production of coke. By-product ovens, on the contrary, have increased in number each year since 1894. The greater advantages and economies of the newer process will continue to operate in the further decrease in beehive ovens.

The history of the construction of beehive and by-product ovens in the United States is shown in figures 134 and 135 and by the tables on the following pages. The reports to the United States Geological Survey by the operators cover the number of ovens in existence and being built at the end of each year and the number abandoned during each year. Beehive ovens may be completely constructed during the 12-month period, or they may be abandoned, and the total shown for any year therefore does not necessarily represent the total of those in existence at the end of the previous year plus the number reported as under construction. Some beehive ovens in Kansas have been idle for years, but they are reported to the Geological Survey as idle, not as abandoned. In all probability, however, few of these ovens will ever be operated again.

The first by-product ovens were constructed in the United States in 1893, and since 1894 not a year has passed without additions to the number in operation. The number of ovens under construction

[1] With beehive ovens are included the rectangular ovens and all modified types in which partial combustion of the coal takes place and no by-products are saved.

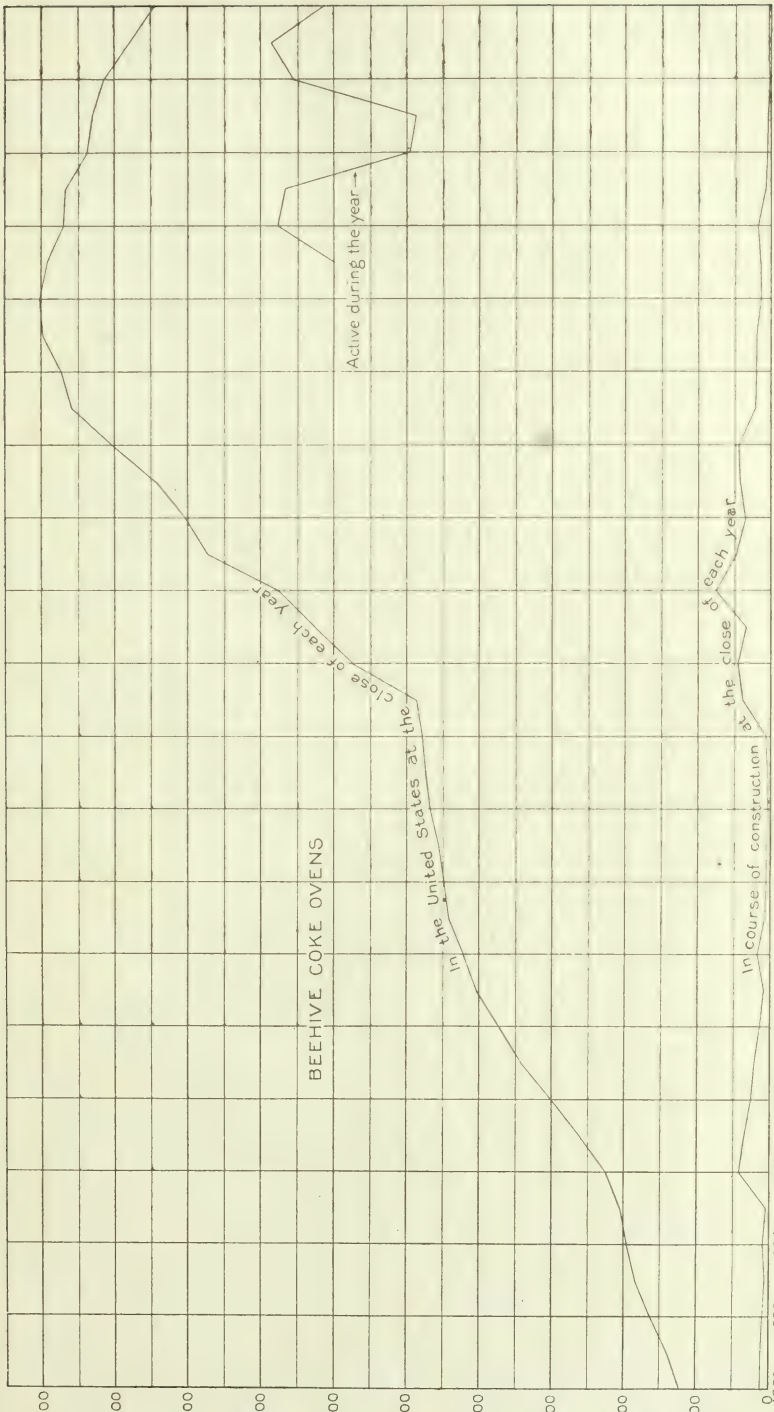

FIGURE 134.—Beehive coke ovens completed and under construction in the United States at the end of each year, 1880–1918.

and the total built at the end of each year are shown graphically in figure 135, and it is interesting to compare these curves with that in figure 133 showing the annual output from these ovens for the same period. Prior to the World War the greatest activity in construction was in the years 1901 and 1910. In 1900 there were 1,096 ovens being built, 80 of which were completed in 1901. In 1901 there were 1,533 ovens, including 1,005 reported in 1900, under construction, 502 of which were put into operation in 1902. This activity was confined mainly to Alabama, Maryland, New York, and Pennsylvania, and most of the ovens built at this time were of the Otto-Hoffman or modified types. Between 1903 and 1909 there was a lull in the construction of by-product ovens. In 1909 large installations of Koppers ovens at Gary, Ind., and of Didier ovens at South Bethlehem, Pa., were begun, but as they were not completed in 1910 they are shown as under construction in the record for that year also. The number of by-product ovens under construction reached a maximum of 2,260 at the end of 1917. On December 31, 1918, the number under construction was 1,815. The number of completed ovens has increased at a rapid rate, the only period in which progress was slow having been in the years 1906 to 1910.

Figure 134 shows the number of completed beehive ovens at the end of each year for the period from 1880 to 1918. The number of beehive ovens under construction at the end of each year is also shown,

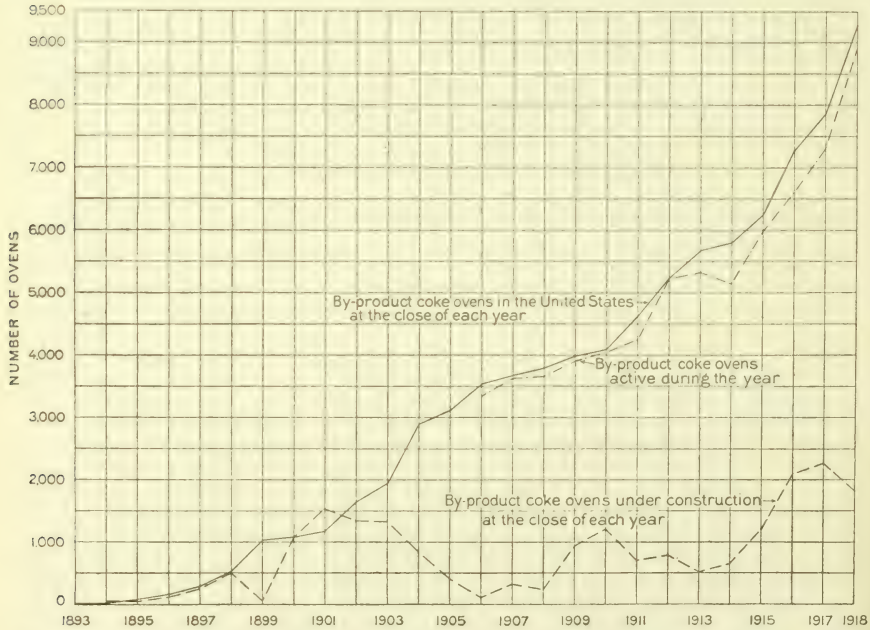

FIGURE 135.—By-product ovens completed and under construction in the United States at the end of each year, 1893–1918, and by-product ovens active during the years 1906–1918.

but it is evident that this record is a very poor index of activity; for, as has been previously noted, beehive ovens are constructed in a comparatively short time and abandoned with equal facility, and an annual statement of those in process of erection furnishes little real information.

From 1880 to 1893 steady progress was made in the erection of beehive ovens, but from 1894 to 1899 there were few additions. From 1900 to 1907, a period of great industrial expansion, particularly in the iron and steel business, the number of beehive ovens increased rapidly, and in 1910 the highest number was reached—the same year, it will be noted, that recorded a large number of by-product ovens under construction. Each succeeding year since 1910 has shown a decrease in beehive ovens, and in view of the present activity in the construction of by-product ovens, there is no reason to expect otherwise than that the trend will continue downward.

Coke ovens in the United States, 1917 and 1918.

CAPACITY OF BY-PRODUCT OVENS.

The capacity of a coke oven naturally depends on the number of hours adopted as standard coking time. Defined as "the maximum quantity of coke of the grade desired by the operator which can be

produced when all conditions are favorable, with all ovens active," the maximum capacity of the by-product ovens in existence on January 1, 1918, was 27,000,000 net tons of coke a year. (See summary of weekly operating reports, p. 1459.) By the end of 1918 it had risen to 33,700,000 tons, an increase during the year of 25 per cent.

In actual practice, however, as the experience of the war period shows (see pp. 1458–1473), operation at 100 per cent of capacity can not be maintained over extended periods. Instead, an average operation of 85 per cent of maximum capacity or at the most 90 per cent appears to be the upper limit of probable performance. Applying these percentages to the maximum capacity of by-product ovens completed on December 31, 1918, gives the following results:

Probable maximum annual yield of by-product coke ovens completed on Dec. 31, 1918, in net tons.

	Coke.	Coal for charge.
90 per cent operation	30,300,000	42,500,000
85 per cent operation	28,600,000	40,200,000

The completion of ovens in course of construction on December 31, 1918, would increase the maximum capacity to a total of 42,100,000 tons of coke a year. The maximum yield to be expected in actual practice would then be:

Probable maximum annual yield of by-product ovens completed and under construction on Dec. 31, 1918, in net tons.

	Coke.	Coal for charge.
90 per cent operation	37,900,000	53,200,000
85 per cent operation	35,800,000	50,300,000

In other words, the end of the year 1918 found the country equipped with plants either built or in course of building capable of producing by-product coke at the rate of 36,000,000 to 38,000,000 tons, or say 37,000,000 tons, a year. It is significant to compare this figure with our annual requirements for coke, because the opinion is held by some in the coke trade that there is a limit to the profitable expansion of the by-product industry. It is reasoned that the construction of new by-product plants will be arrested when a total capacity is reached sufficient to supply the demand for coke in years when business is dull, leaving to the more elastic beehive industry the task of meeting the additional demand in years when business is active. Whatever may be the merit of this reasoning, it does not appear that the construction of by-product ovens had reached the saturation point at the end of 1918. Only twice in the last decade [1] has the production of coke fallen below 37,000,000 tons, the figure of capacity derived above for plants built and under construction on December 31, 1918. This quantity, 37,000,000 tons, is 66 per cent of the coke produced in

[1] In 1911 the output was 35,550,000 tons; in 1914 it was 34,560,000 tons.

1918, the largest quantity ever used by the country in one year. It is 63 per cent of the coke required for producing 49,666,000 gross tons of pig iron, the annual capacity of the coke-burning blast furnaces completed or under construction on December 31, 1918, according to the annual statistical report of the American Iron and Steel Institute, the coke consumption being taken at 2,375 pounds per gross ton of iron. It is 62 per cent of the country's total requirements for coke in the war year 1918, as estimated by the United States Fuel Administration, less sales of gas-house coke, amounting to 1,814,000 tons.

BY-PRODUCT PLANTS.

A list of by-product coke plants, with notes regarding types of ovens, dates of installation, and uses of by-products, is given in the following table. Similar data for ovens under construction at the end of 1918 are given in another table. Although used primarily as a source of coke for iron-furnace operations and for the most part built by the iron-producing interests, a number of these plants have been installed with the main purpose of producing domestic gas for municipalities.

	Newburg	do	60	Semet-Solvay		

VALUE OF COKE PRODUCED.

CHANGE IN SCHEDULES.

A change in the form of inquiry used, already referred to, renders it difficult to compare the value of coke in 1918 with that in earlier years. A considerable proportion of the coke produced in the United States is made in ovens or retorts operated by large corporations that not only mine the coal and make the coke but also operate blast furnaces and steel mills which consume the entire product of the ovens. Under such conditions the fixing of a value upon the coke and upon the coal consumed in making it is purely arbitrary. By some corporations the coke is charged to the furnace department at cost; by others a percentage of profit is added or the reported value is based on what the coke would cost if purchased.

Formerly each operator was asked to estimate the value of the coke produced but not sold, but for some years prior to 1918 it had been apparent that the figures thus obtained were of questionable accuracy, the more so as the substitution of by-product for beehive ovens steadily increased the proportion of the total quantity for which only estimated values were possible. These considerations led to a change in the statistical schedule in 1918. Copies of the 1918 schedules are reprinted on page 1524. Instead of requesting the operator to estimate the value of the coke used but not sold, the schedule asked separately for the production, the quantity sold, and the value of the quantity sold, all of which could be accurately measured. The result of the 1918 inquiry is shown in detail in the first of the accompanying tables.

GENERAL STATISTICS.

Of the 56,478,000 tons of merchantable coke produced in all types of ovens, about 40 per cent was not sold but used by the producer, the great bulk of this being undoubtedly blast-furnace coke.[1] A total of 33,973,000 tons was sold, of which 27,364,000 tons was furnace coke, 3,861,000 tons foundry coke, and 2,748,000 tons domestic and other coke. The proportion used by the producers was naturally much greater for by-product coke than for beehive coke. Two-thirds of the by-product coke was consumed by the companies that produced it. The total sales of by-product coke amounted to 8,316,000 tons, valued at $65,548,000. Of the beehive coke produced, on the other hand, only one-sixth was consumed by the producing companies. The total quantity so consumed was 4,885,000 tons. Alabama, Colorado, Ohio, and parts of Tennessee and southwestern Virginia are the only localities where the proportion of the output consumed by the producers is large.

Interest attaches to the relative proportions of the sales for furnace, foundry, and domestic use. The sales of furnace coke constituted 90 per cent of the total quantity marketed by beehive operators but only 50 per cent of the by-product coke. Foundry coke constituted 9 per cent of the quantity marketed from beehive ovens and 20 per cent of the by-product coke, and the total sales of by-product foundry coke were within 600,000 tons of the sales of

[1] The figures of sales and the quantity used by producer are almost invariably exclusive of breeze.

beehive foundry coke. Sales of beehive coke for domestic purposes constituted 1 per cent of the total beehive coke sold, while sales of domestic by-product coke amounted to 2,537,000 tons, 12 times as much as the domestic beehive coke, and formed 30 per cent of the total sales of by-product coke.

In the second of the following tables is given the average price realized per ton f. o. b. ovens on each grade of coke sold in each State. The figures are obtained by dividing the total receipts by the number of tons sold. It will be noted that the values of retort coke range consistently higher than those of beehive coke. As explained in previous reports, this is due not to the superior quality of by-product coke but to the fact that the retort ovens are installed at or near the centers of consumption, where markets for the gas and other by-products as well as for the coke are available, but at considerable distances from the coal mines. Hence the expenses of transportation are borne by the coal and are added to the value of the coal as charged into the ovens, and an equivalent value is necessarily added to the coke. The beehive and similar types of ovens, on the other hand, are in the immediate vicinity of the mines, and the expenses of transportation are borne by the coke; the beehive coke thus costs the ultimate consumer as much as the apparently higher-valued retort coke.

Throughout the year 1918 maximum prices on coke fixed by the Fuel Administration under the Lever Act were in force. The theory underlying the prices was that the price of coke should bear a reasonable relation to prices of iron and steel products fixed by the War Industries Board and agreed to by the steel makers. A base price for furnace coke of $6 a net ton f. o. b. ovens in the Connellsville region was in effect throughout the year. A differential of $1 a ton was allowed for foundry coke, the Connellsville base being $7. In fixing maximum prices for by-product coke regard was had for the normal relation of the by-product price to the Connellsville region price. Normally the sales price of by-product coke is calculated on the basis of the prevailing Connellsville price plus freight charges from Connellsville to the point of consumption minus freight charges from the by-product coke plant to the consumer. For a discussion of coke prices during 1918 the reader is referred to the chapter on prices of coal and coke, 1913–1918, contained in this volume, pages 15–115, and to Part I of the report of the distribution division of the United States Fuel Administration, pages 88–90. The orders fixing prices on coke are to be found in "General orders, regulations, and rulings of the United States Fuel Administration."

In comparing the average realization figures shown in the accompanying table with the Government maximum prices, it is to be remembered that shipments on bona fide contracts entered into prior to September 22, 1917, were not affected by the Government prices. Many sales during 1918 were therefore consummated at prices below or above the maxima fixed by the Fuel Administrator.

In order to maintain the continuity of the Survey's statistical record of coke, an estimated figure of total value at the oven of all coke produced has been prepared. Assigning a value to the coke consumed by the producer comparable to the average realized price on the coke actually sold gives an approximate figure of $382,000,000. In comparison with the total for 1917 this was an increase of $84,000,000, or 28 per cent. Beehive coke increased in total value 18 per cent, rising from $160,000,000 to $189,000,000. The value of by-product coke increased even more sharply. The 1917 output was valued at $139,000,000. For 1918 it is placed at $193,000,000, an increase of 39 per cent. The greater increase in the value of by-product coke was attributable largely to the increase in quantity produced, for the average value per ton rose only $1.24 as compared with $1.40 for beehive coke. The average realized price for all beehive coke was $6.21, for by-product coke $7.42. The weighted average for both types was $6.77.

Average prices realized for beehive and by-product coke, 1908–1918, per net ton.

[a] Included under "Combined States." [b] Values estimated on basis of sales.

PRICES IN CONNELLSVILLE REGION.

The most active coke market in the United States is the Connellsville district of Pennsylvania, and as the prices for the coke from that district govern largely those in other places, the following table is given showing Connellsville prices, by months, during the years 1915, 1916, 1917, and 1918. These prices are the quotations for Connellsville coke at the ovens given in the current issues of the Iron Age. The spot prices are those quoted for immediate delivery, and the contract prices, as the term implies, are those established to cover the requirements of the buyer for a specified period, usually for six months. The relation of supply to demand governs to a large extent, of course, the range of prices for both spot and contract coke. When demand is strong and a shortage of supplies is felt, as in the early months of 1913, the prices for spot coke were above contract prices. Normally the greater part of the coke of this region changes hands on the contract basis.

In 1916 prices per ton for both furnace and foundry coke were more than three times the top quotations for 1915 and were more than twice the previous maximum of 1913. This upward swing of prices continued in 1917, spot furnace coke reaching a maximum quotation of $16 in July and spot foundry coke a maximum quotation of $14 in March and again in July and August. On September 22 a presidential order was issued, effective September 24, establishing $6 a net ton as a maximum price for both grades of coke, and a subsequent order of the Fuel Administrator, effective November 10, 1917, set maximum prices of $6 a net ton f. o. b. for furnace coke and $7 a ton for foundry coke.

The Connellsville Courier is authority for the statement that prices realized from sales of spot coke in August, 1917, averaged for the region $13.42 a ton for furnace coke and $14.25 for foundry coke—a record for the region; and, according to the reports received by the Geological Survey, the average prices realized for the Connellsville and Lower Connellsville districts were, respectively, $3.95 and $4.85 a ton in 1917, compared with $2.42 and $2.60 a ton in 1916, increases of 63 and 87 per cent.

Throughout 1918 the Fuel Administration prices of $6 a net ton f. o. b. ovens for furnace coke and $7 a ton for foundry coke were continued in force.

The average realized prices in 1918, reported to the Geological Survey by operators in the Connellsville region, were $5.80 for furnace coke and $7.20 for foundry coke. That these averages should not agree exactly with the Government price was to be expected, inasmuch as considerable quantities of coke continued to move at prices fixed by bona fide contracts negotiated before the issuance of the original price order.

For a historical review of prices during the war the reader is referred to the chapter on "Prices of coal and coke, 1913–1918," pages 15–115.

Prices of Connellsville furnace and foundry coke per net ton at the ovens, 1915, 1916, 1917, and 1918.

COAL USED IN THE MANUFACTURE OF COKE.

GENERAL STATISTICS.

The quantity of coal consumed in making coke reported in this chapter each year is at considerable variance with the quantity reported as made into coke in the chapter on the production of coal. The reason for this discrepancy is that in the chapter on coal the figures for the quantity made into coke take into account only the coal which is coked at the mines. The coal shipped to ovens at a distance, which includes nearly all the coal charged into by-product ovens reported by the coke manufacturers, is included by the coal operators in their shipments and not in the quantity they report as made into coke.

As a consumer of soft coal the coke industry ranks next to the railroads and the group of general industrial plants. In 1917 and again in 1918 about 15 per cent of the bituminous coal produced was consumed in the manufacture of coke.

The total quantity of coal consumed in making coke in 1918 was 85,028,000 tons, of which 48,160,000 tons, or 56.6 per cent, was used in beehive ovens and 36,868,000 tons in by-product ovens. In comparison with the figures for 1917 this was an increase in total consumption of 1,276,000 tons, or 1.5 per cent. The cost of the coal used showed a much greater increase, rising from $221,309,000 to $267,312,000. The average cost of the coal per ton laid down at the oven was $3.14 in 1918, as against $2.64 in 1917. Not all of this figure represented revenue to the producer of the coal, however, for in the case of most by-product plants it includes the freight rate from the mine to the place of use.

The average quantity of coal used per ton of coke produced in 1918 was 1.505 tons, a slight decrease as compared with the average in 1917. Like many other averages, however, this figure is capable of misinterpretation; the decline in average coal consumption indicated was not due to improved performance in either beehive or by-product practice (see pp. 1505–1506), but rather to the progress in substituting by-product for beehive coke, the former requiring less coal than the latter. The average consumption of coal per ton of coke increased in 1918 in both branches of the industry.

In the fifth column of the acompanying table is shown the average cost of the coal used per ton of coke, obtained by multiplying together the figures in the third and fourth columns. It is significant to note not only the rising cost of the coal per ton of coke but also the great variation in cost in different localities. The average cost for the whole country in 1918 was $4.73 a ton. The lowest coal cost was $3.35 at the beehive plants of New Mexico; the highest $9.07 for the State of Washington.

The high coal costs in the States where by-product coke is made are due to the freight charges involved in transporting the coal from mine to oven. Among the larger producers Pennsylvania, though containing many by-product ovens, was easily lowest in point of coal costs, with an average of $3.72.

Coal used in the manufacture of coke in the United States in 1917 and 1918.

1917.

COAL FOR BY-PRODUCT COKE.

The quantity of coal consumed in the manufacture of by-product coke in 1918 is shown in the following table, with comparable statistics for the 10 years preceding. Most of the by-product plants are in the iron-producing centers and are at a considerable distance from the coal fields; in fact, by-product coke was made in five States in 1918 in which there are no coal deposits and in six others in which no high-grade coking coal is found. It is the usual practice to use a mixture of coals in by-product ovens, and a favorite combination seems to be a high-volatile or "gas" coal from eastern Kentucky, from the Kanawha or Fairmont district of West Virginia, or from southwestern Pennsylvania, with low-volatile or "smokeless" coal from the Pocahontas and New River fields of West Virginia or from central Pennsylvania. It thus happens that a large part of the coal used comes from the mines in West Virginia, and West Virginia coal is used at places as far distant as Illinois, Indiana, Wisconsin, and Minnesota.

The origin of the coal used in 1917 by the by-product plants in each State is given in the second of the following tables. Comparable statistics for 1918 are not available.

Coal used in the manufacture of by-product coke in the United States, 1908–1918, in net tons.

The extension of by-product coking has intensified the demand for both the low-volatile and high-volatile coals used in the mixture charged into the ovens. Aside from deposits in the Southwest and the Rocky Mountains, which are geographically inaccessible to most of the by-product plants, the deposits of low-volatile coal in the United States are confined to the belt of semibituminous coals which extends, with some interruptions, along the eastern margin of the great Appalachian coal basin from the Snowshoe district of Pennsylvania to southern West Virginia. These coals, known to the trade as smokeless, were already much prized for domestic use and for raising steam, particularly under ships' boilers. They were much in demand for export, partly because they lie nearest the coast, partly because alone among American coals they compare favorably with the best British and German coals. The provision of the necessary low-volatile coals for by-product ovens was therefore a continuing problem during the war period, especially as they must be transported long distances to reach the by-product plants in Indiana, Illinois, Michigan, and Minnesota.

No less difficult was the problem of securing the high-volatile constituent of the by-product mix. The type of coal desired for this purpose, besides possessing the coking quality, is high in the volatile constituents from which the by-products are derived and low in ash and sulphur. This type of coal is best developed in the East near the western limb of the Appalachian coal basin, notably in western Pennsylvania, parts of southern West Virginia, and eastern Kentucky. Coals meeting these requirements are also in demand for the manufacture of coal gas and for use as "gas" coal in open-hearth furnaces. To meet the growing demand for gas and by-product coals, extensive developments have been made, particularly in eastern Kentucky, where the growth in mine capacity has taxed to the limit the ability of the railroads to transport the product.

So acute was the problem of the supply of coal for by-product ovens that a special inventory of sources of supply was undertaken by the United States Fuel Administration. The following table presents the results of tabulating the production in 1917 of mines listed as producing coal suitable for the manufacture of by-product coke. The tabulation indicates that in 1917 these mines produced 122,000,000 tons of high-volatile by-product coal and 55,000,000 tons of low-volatile coal suitable for coke manufacture, a total of 177,000,000 tons. Of this total, only a sixth—31,506,000 tons—was carbonized in by-product ovens in 1917. It will be noted that the inventory was limited to districts east of the Mississippi. By-product coal, both high and low volatile, is produced west of that river, but the quantity has not been ascertained. Furthermore, it should be remembered that recent experiments have shown that coke suitable for some purposes can be made in the by-product oven from coals hitherto considered unfit for by-product use, such as those of Indiana and Illinois, and developments along this line would, of course, make available large quantities of coal produced in other localities than those listed below. The list of mines was determined by a committee of the Fuel Administration staff familiar with by-product coke-oven practice, after correspondence with all the operators of by-product ovens and many producers of coal. The classification as between first and second grade was not made in accordance with exact stand-

ards or hard and fast rules, but was determined largely by the experience of users verified by the analyses of the coals. The following notes describe briefly the standards used in the classification: [1]

Answering your inquiry [of November 21, 1918], we have no exact standard by which coal is arbitrarily classified in the three different grades.

In order to be classed in the first grade the ash should not exceed 8 per cent as a maximum and the sulphur should not exceed 1 per cent in the coke. This allows for a considerable variation of sulphur in coal, as a much larger percentage will burn off in coking in some coals than in others.

Medium grade should analyze not more than 10 per cent in ash and coke made from this coal should not exceed 1.20 [per cent] in sulphur.

Any coals that are higher in sulphur or ash than second grade we have classed in the third grade and these coals we consider unsuitable for by-product use.

In addition to the analysis there is also a physical structure of the coke to be considered, and even though the analysis would class a coal as first grade, if it did not make coke of good structure, we would place this coal in a lower grade.

PREPARATION OF COAL USED IN THE MANUFACTURE OF COKE.

Coke for iron furnaces must be as free from ash and sulphur as possible. Dirty coals are therefore cleaned by washing before being charged into coke ovens, and in 1918 the coal so treated amounted to 15,579,051 tons. Of the quantity washed, 8,577,723 tons, or 55 per cent, was run of mine, and the remaining 45 per cent was slack. Two-thirds of the coal used for making coke in New Mexico and nine-tenths or more of that used in Alabama, Colorado and Tennessee, was washed; in Georgia and Washington it was all washed.

[1] Informal communication from C. C. Marvel, manager, section on by-product coke and artificial gas plants, United States Fuel Administration, Nov. 22, 1918.

In some of the coal fields the slack is screened out and used in making beehive coke, and the lump coal is shipped to market. The total quantity of slack used in 1918 was 13,154,000 tons, more than half of which was washed. The by-product ovens generally use run of mine coal of the best quality, and practically all the coal made into coke in ovens of that type, outside of Alabama, Colorado, Washington, and Tennessee, was unwashed run of mine coal. In New York also some coal used in by-product ovens is washed. In 1918 the proportion washed was 16.4 per cent.

The gradual change from beehive to by-product ovens is having its effect on the preparation of coal used in making coke. The proportion of washed coal has steadily decreased from 21.4 per cent in 1915 to 19.5 per cent in 1916, 18.5 per cent in 1917, and 18.3 per cent in 1918. The quantity of slack used has likewise been decreasing both relatively and absolutely. Of the coal charged in 1916, 17.9 per cent, or 14,611,000 tons, was slack; in 1917, 16.1 per cent, or 13,456,000 tons; and in 1918, 15.4 per cent, or 13,154,000 tons.

Coal used in the manufacture of coke in 1917 and 1918, by kinds, in net tons.

YIELD OF COKE FROM COAL.

The yield of coke from coal varies with the coking time, the type of oven, the extent to which the coal used possesses the coking quality, and the analysis of the coal. The figures shown in the following table are averages obtained by dividing the total quantity of coke produced in each district by the total of the coal charged.

On the effect of the first of these factors, variation in the coking time, the records of the Survey throw no light.

The average yield from by-product ovens in 1918 was 70.5 per cent; the average yield in beehive ovens was reported at 63.3 per cent. The difference of 7.2 per cent in favor of the by-product process means an average recovery in by-product ovens of 144 pounds of coke more than the average in beehive ovens for every ton of coal charged. Had all the coke produced in 1918 been made in by-product ovens, the increased yield would have amounted to 3,466,000 tons.

This comparison, however, fails to do entire justice to the by-product oven in that it does not take into account the breeze produced. Data are lacking to compare accurately the total quantities of breeze formed in beehive and by-product coking, but it is possible to compare the quantities of breeze put to some use in the two industries, and the comparison is favorable to by-product practice. In addition to merchantable coke, the by-product operators in 1918 sold or utilized 1,999,370 tons of screenings or breeze. Beehive operators regarded as useful product only about 124,000 tons of the breeze formed. The recoveries of screenings and breeze at by-product plants in 1918 amounted to 108 pounds per ton of coal charged; at beehive plants the average quantity utilized was only 5 pounds. Expressed in terms of percentage of coal charged, the recoveries of useful breeze were 5.4 and 0.2 per cent for by-product and beehive ovens, respectively. Including the screenings and breeze, therefore, the recovery in useful form of solid carbon residue averaged 75.9 per cent in by-product ovens, as against only 63.5 per cent in beehive ovens, and it is a fair statement of fact that the coking of coal in beehive ovens in 1918, over and above the loss of the volatile products, cost the country 5,950,000 tons of solid fuel which would have been available had all the coal been treated in by-product ovens.

The table also discloses marked differences in the average recovery from one locality to another, irrespective of the type of oven. Thus into the average of 63.3 per cent for all beehive ovens went not only the maximum of 65 per cent in Pennsylvania but also the much lower figures of 53.6 per cent in Tennessee, 56.3 in Utah, 56.4 in Kentucky, and 57 in New Mexico. In general the yields in the Northern Appalachian region ran over 60 per cent. In the Southern Appalachian region and the Southwest the averages were less than 60 per cent. Of the western producers, only Colorado and Washington reported yields in excess of 60 per cent. These differences are attributable to the type of coal used. Not only do some coals coke more easily than others, but variation in the volatile content has a marked influence upon the percentage recovered. Thus the low-volatile coals of the Flat Top and Tug River districts of southern West Virginia, although possessing the coking quality to a high degree, gave an average yield in beehive ovens of only 59.3 per cent in 1918, whereas the higher-volatile coals of the Connellsville region

yielded 66.3 per cent. The difference is caused in part by the fact that to provide the heat necessary for the beehive coking process, a considerable part of the fixed carbon in the lower-volatile coals is burned away. The combustion of the rich gaseous content of the high-volatile coals furnishes heat enough for the coking process with but little draft on the fixed carbon. From this fact it arises that the advantage of the by-product oven over the beehive oven is most pronounced when the coal used is a low-volatile coal.

Average yields in by-product practice ranged in 1918 from a minimum of 67.2 per cent in Ohio to a maximum of 82.2 per cent in Massachusetts. Variations in the mixture of coals used, in the coals themselves, and in coking practice, as well as in the type of oven, enter into these differences in yield.

The trend of the average recovery was steadily downward from 1915 to 1918, in both beehive and by-product practice as shown by the averages in the following tables. To what extent this was due to changes in the character of the coal used is uncertain. Many plants were forced during the war to use at times coal of unsatisfactory quality.

Average percentage yield of coke from coal in beehive and by-product ovens, 1915–1918.[a]

Year.	Beehive.	By-product.
1915	65.1	72.0
1916	64.4	71.9
1917	63.5	71.2
1918	63.3	70.5

[a] Screenings and breeze excluded in calculating the yield.

During the same period the average yields of certain of the by-products per ton of coal charged have also been decreasing.

DISTRIBUTION OF COKE.

SHIPMENTS OF BEEHIVE COKE, BY RAILROADS AND WATERWAYS.

The following tables, showing the quantity of beehive coke shipped by originating railroads and waterways in 1917 and 1918, are compiled from reports of the operators and therefore in some respects do not agree exactly with the records of the carriers themselves. As beehive ovens are almost invariably located at the mines, the great bulk of the beehive coke produced must be transported some distance in order to reach the place of use. In 1917 91.6 per cent of the entire output of beehive coke was loaded for shipment by rail or water; in 1918 the proportion was still higher, amounting to 93.8 per cent. In fact, in many localities, notably Georgia, Kentucky, New Mexico, West Virginia, and the far West, practically the entire output is shipped.

In other localities the furnaces that consume the coke are also located at the mines, and considerable quantities of coke produced are used locally without appearing as railroad shipments. This is notably true in Ohio, parts of Tennessee, and the Birmingham district of Alabama. In Pennsylvania also the local consumption is significant, the shipments ranging from 92.4 per cent of the output in 1917 to 87.5 per cent in 1918.

Water-borne shipments of beehive coke are confined to movement down Monongahela River from the Connellsville region. In 1917 shipments on the Monongahela were reported by the producers as 169,000 tons, or 0.6 per cent of the total output of beehive coke. In 1918 this movement increased more than tenfold and amounted to 1,839,000 tons, or 6.4 per cent. A striking feature of the statistics of rail shipments is the concentration of the movement over certain of the larger carriers. The five leading railroads—the Pennsylvania, Monongahela, Baltimore & Ohio, Norfolk & Western, and Pittsburgh & Lake Erie—together loaded about three-fourths of all the coke produced. This fact is taken advantage of by the Geological Survey in estimating the current production of beehive coke. Weekly statements obtained from 26 of the principal carriers, which load on the average 94 per cent of the entire output, are used as a base which is built up to terms of total production by allowing for shipments by water, shipments over the smaller roads, and the tonnage used locally. (For weekly and monthly estimates of production obtained in this way, see pp. 1453–1454.)

Beehive coke shipped by originating railroads and waterways in the United States in 1917 and 1918, by States.

FOREIGN TRADE IN COKE.

The foreign trade of the United States in coke, although modest in comparison with the 7,100,000 net tons exported from pre-war Germany, is an appreciable item in our foreign commerce. The give-and-take of trade makes of the United States both an importer and an exporter of coke. The balance, however, is heavily on the side of the exports, which in 1918 exceeded the imports by 1,658,000 tons, equivalent to 2,600,000 tons of coal. This was less than 0.5 per cent of the production of coal for the year, but about 9 per cent of the net exports of coal in all forms.

Before the outbreak of the World War our exports of coke averaged about a million tons a year. The war caused a temporary depression in the export movement, which gave place late in 1915 to a rapid expansion that carried the total exports to 1,175,000 tons in 1916, 1,409,000 tons in 1917, and 1,688,000 tons in 1918. The value of the exports in 1918 was $11,861,000.

The great bulk of our export coke goes to Canada and Mexico. In 1918 those two countries together took 92 per cent of the total exported. The 1,200,000 tons supplied to Canada went almost entirely to Ontario and lower Quebec, most of it by rail through Buffalo and Detroit. The volume of this export movement to Canada is often overlooked by the coal trade. These shipments in 1918 represented a coal equivalent of 1,870,000 tons, no mean item even when compared with the 5,000,000 tons of anthracite and 18,000,000 tons of raw bituminous coal exported to Canada.

Shipments of American coke to Mexico have averaged in recent years about a third of a million tons. The shipments in 1918 are reported at 359,744 tons, valued at $2,648,599. They were destined largely for lead and copper smelters in northern Mexico and left the United States through the customs districts of Arizona, San Antonio, and El Paso.

Sea-borne exports of coke from the United States are small and confined exclusively to the Atlantic and Gulf coasts. The principal port of shipment is Baltimore, from which in 1918 a total of 92,188 tons was forwarded. Occasional cargoes of coke are exported from

Hampton Roads, Philadelphia, and Florida ports. Water-borne exports of coke go almost entirely to South America, there to be used in metallurgy. Among the South American Republics Chile ranks first as a purchaser of American coke, followed in order by Peru, Cuba, Argentina, and Brazil.

From the table of exports, by months, it will be noted that the foreign shipment of coke is fairly regular, displaying no pronounced seasonal rhythm.

Imports of coke, which ran about 125,000 tons a year before the World War, have now shrunk to insignificant proportions. In 1918 the imports were 30,168 tons, valued at $221,880. Most of the coke imported comes from British Columbia and is used by metallurgical works in Montana and Idaho. Occasional shipments are received from Ontario through the port of Buffalo.

Coke exported from the United States, 1909–1918.

COKE BREEZE.

In the manufacture of coke a certain amount of fines not suited for foundry or furnace use and but little in demand as a domestic fuel is inevitably produced. This material, known to the trade as breeze, was defined by the Fuel Administration as follows, irrespective of whether produced in beehive or by-product ovens or in coal-gas retorts: (*a*) All small coke that is left after loading coke into cars by means of forks if disposed of without further screening or sizing, (*b*) any portion of this coke that remains after removing the prepared sizes, (*c*) any undersized coke that is left after removing the metallurgical coke, the foundry coke, or the prepared sizes by screening.

The characteristics of breeze are fine texture, high ash content (sometimes 20 per cent or more), and low density. Although containing considerable heat units per pound and burning without smoke, it can be used to advantage only on specially constructed grates.

It is essentially a low-grade fuel presenting much the same problem as steam sizes of anthracite.

It has in the past been frequently proposed to utilize breeze as a raw material for fuel briquets, and at least two plants in the United States have made the attempt on a commercial scale. The first was a plant of the United Gas Improvement Co. at Point Breeze, Philadelphia, which was operated primarily to utilize the breeze produced at the retorts of the company's coal-gas plant. The briquets were used in the associated water-gas plant, and no attempt was made to sell them on the open market. Another briquetting plant designed to operate on coke breeze was constructed by the Semet–Solvay Co. at Delray, Mich. The briquets were designed for household use. At this plant, as at the Philadelphia plant, the breeze was mixed with bituminous coal slack. Neither plant made a commercial success of the breeze briquets, chiefly because of the injurious effect of the breeze on the bearings and other parts of the machinery. At the United Gas Improvement plant breeze was abandoned in 1909, and anthracite fines used instead. The operations at the Delray plant were also short-lived, the latest production reported being in 1909.

The abrasive character of coke breeze has continued to militate against its use for fuel briquetting and, so far as is known to the Geological Survey, no plant in the United States is employing it for this purpose at the present time.

A limited market for coke dust is found in the zinc-smelting industry, where it is used as a reducing agent in the clay retorts.

No accurate measure exists of the total quantity of breeze formed each year in the manufacture of beehive coke. The fines produced in beehive coking are given by Fulton as from 2 to 3 per cent in the Connellsville region, and Eavenson states that 5 to 8 per cent is common in the Pocahontas field. Parker in 1909 estimated the total quantity of fines as at least 2,000,000 tons a year. For the most part breeze has been treated by the beehive operator as so much waste matter and allowed to accumulate in piles or dumps in the manner of the old anthracite culm banks. Under the stimulus of the high prices which have prevailed since 1916 these old dumps have been reworked to some extent. Containing originally many fragments of a size large enough for domestic use, the old breeze piles have furnished limited quantities of domestic fuel. The practice assumed sufficient proportions during the war to be made the subject of special orders of the Fuel Administration which prohibited the reclaiming of old breeze dumps except under permit from the coke bureau of the Fuel Administration. This action was taken on the ground that (*a*) labor was being diverted from the production of fresh coke urgently needed for the manufacture of munitions, and (*b*) the transportation system, already overtaxed, was being burdened with the task of hauling a low-grade fuel. The maximum price allowed for such mixed domestic coke as was reclaimed from breeze dumps under permit issued in conformity to this order was $5.50 a ton. The maximum price permitted on coke breeze itself was one-half the price fixed for blast-furnace coke in the same district or in the Connellsville region, a maximum of $3 per net ton of breeze f. o. b. ovens. How much breeze was actually sold at this maximum does not appear.

In an effort to ascertain the quantity of breeze formed each year, the Geological Survey added to its beehive-coke schedule in 1918 an

inquiry asking for the "quantity of screenings and breeze produced." From the replies it is clear that by no means all the fines formed in the manufacture of beehive coke were reported. Many operators reported no breeze at all, and those that did report generally mentioned small quantities. It seems clear that beehive operators as a class are not yet accustomed to think of breeze as a "product" or even as a by-product, but rather regard it as so much waste. The total quantity of breeze and screenings reported as produced at beehive ovens in 1918 was 124,000 tons, most of it from Pennsylvania. This is believed to represent breeze that brought some return to the operator or was used by him about the plant. The figures are published for what they are worth in the table on page 1494.

At retort coke ovens, on the other hand, breeze is now a recognized by-product. The majority of by-product plants are close to centers of population in which there is an expanding demand for both household and industrial fuel. Moreover, the operation of the by-product plant itself and of the iron and steel works commonly associated with it offers many opportunities for the utilization of breeze. It may be used as a boiler fuel to provide power, heat, or process steam. So numerous are the demands for boiler fuel about a typical by-product iron and steel plant that there is little incentive to dispose of the breeze on the open market.

The Geological Survey has collected statistics of breeze at by-product plants covering the last three years. The first of the accompanying tables presents data for 1916 and 1917. In those years the inquiry was so phrased as to ask for "breeze obtained and sold." The companies were requested to treat as sales the quantity used about the by-product plants or delivered to associated iron and steel works, and to assign a cost-keeping value to the breeze so used. The value was necessarily arbitrary but is still significant. The returns indicate a total credit derived from breeze and applicable to the expenses of the coking operations amounting to $1,700,000 for the 1,031,000 tons of breeze reported in 1916. This was an average value of $1.65 a ton. In 1917 the quantity reported was 1,496,000 tons, valued at $2,348,000, or $1.57 a ton. How much of this represented sales on the open market is unknown.

The data collected in 1918 are shown in the second of the following tables. Instead of asking, as in 1917, for the quantity obtained and sold, the inquiry in 1918 asked for the quantity produced. The replies indicated a total recovery in the form of screenings or breeze of almost 2,000,000 tons, the distribution of which from State to State followed closely the output of by-product coke. The value of the breeze produced in 1918 is not known. The maximum price for breeze when sold was fixed by the Fuel Administration at one-half the price fixed for run of oven coke.

The statistics of breeze reveal an additional point of superiority of by-product ovens over beehive ovens not always realized. To the beehive industry breeze is still a waste product, seldom utilized. To the retort-oven operator it is one of many valuable by-products. The by-product industry not only saves the volatile constituents in the coal and secures a higher percentage yield of merchantable coke but it also puts to good use some 2,000,000 tons of solid fuel, or about 5 per cent of the coal carbonized, which in beehive practice would be thrown away.

Coke breeze obtained at by-product coke plants, 1916 and 1917.

BY-PRODUCTS OBTAINED IN THE MANUFACTURE OF COKE.

The war-time demand for the by-products of coal carbonization lent a powerful stimulus to the development of by-product coking in America, and the expansion was not confined to the United States, for Canada also built new by-product plants. In the four years from 1915 to 1918 the output of by-product coke in the United States increased more than in the two decades from the building of the first by-product oven at Syracuse to the outbreak of the World War. The war period was not only marked by a great activity in the building of retort ovens, but also by the recovery on a large scale of a whole new set of valuable products—the light oils and derivatives—which had hitherto been left in the gas, although extracted in small quantities from the tar. The extraction of these new products—sold at prices that reached 15 times the pre-war level—was the chief cause of the extraordinary increase in the value of by-products of coke manufacture—from $17,000,000 total value of by-products produced in 1913 to $75,000,000 value of by-products sold in 1918.

AVERAGE YIELD OF BY-PRODUCTS.

The quantities of the several by-products recovered per ton of coal vary with the efficiency of the recovery system, the quality of the coal, the coking time, and the relative emphasis on coke or on

the volatile products as objectives in the carbonization process. In 1918 the average yield at all plants was as follows:

Average yield of by-products per net ton of coal charged in by-product ovens, 1918.

Coke	pounds..	1,410
Tar	gallons..	7.1
Ammonium sulphate (or equivalent)	pounds..	18.9
Light oil	gallons..	2.4
Gas:		
Total	cubic feet..	10,444
Surplus sold or used	do....	4,295
Burned in coking process	do....	5,720
Wasted	do....	429

These ratios of by-products recovered per ton of coal charged are considerably below the maximum attainable by the best practice under favorable conditions. There was great variation in the recoveries at individual plants. The tar extracted ranged from a minimum of 4.2 gallons to a maximum of 12.3 gallons; the ammonium sulphate from 10.6 to 24.9 pounds; the crude light oil from 0.3 to 4.6 gallons. The ratios are thus weighted averages of the actual recoveries with the existing plants and under the conditions prevailing in 1918. To some extent those conditions were abnormal, particularly in the first four months of the year. Operating time was irregular, coal supplies were uncertain, and it frequently happened that the coke plants were forced to take coal of inferior quality. In spite of these irregularities the average yield of ammonia and of light oil was, if anything, larger than in 1916 and 1917. The 1918 averages may be accepted as the best available indicator of what may be expected in the near future from the country's present equipment of by-product ovens. Improvement in practice and the gradual replacement of old with new plants should gradually raise these ratios nearer the level of the present best practice.

BY-PRODUCTS OBTAINED IN 1918.

A change in the form of inquiry used in collecting statistics for 1918 makes it difficult to compare the returns for that year with those for 1917 and earlier years. In 1918, for the first time, the production and sales were asked for separately, and the only figures representing value collected were those giving the value of the products sold, including coke and surplus gas used about the same establishment. From the results of the inquiry, shown in the following table, it will be seen that there is in many items a considerable difference between the quantity produced and the quantity sold, the latter being usually somewhat the smaller. The difference may be due to one of three causes: (1) Part of the product may be consumed about the works, as, for example, tar burned as fuel; (2) the product may be refined or used in some manufacturing process on the premises and the finished product sold, as, for example, crude light oil delivered to the benzol plant; (3) the product may be stored awaiting transportation or a favorable moment to sell. After the armistice was declared, for example, the prices of ammonia and the group of light oil products broke, and stocks were accumulated at most plants. Of course a rise in price may sometimes cause an opposite effect, with drafts on stocks and sales in excess of production for a given period.

By-products obtained from coke-oven operations in 1918.

[a] Includes liquor and sulphate sold on pound basis of NH_3.
[b] Includes sodium ferrocyanide, pyridin oil, nut coke, drip oil, spent oxide, residue, coal tar paint, and wash oil.

The tar obtained in 1918 was reported as 263,299,470 gallons, an average recovery of 7.1 gallons per ton of coal charged. The quantity sold was 200,233,002 gallons, valued at $6,364,972, an average value of $0.032 a gallon. Coke-oven tar and its sister product coal-gas tar—obtained from coal-gas plants—are one source of the well-known "coal-tar derivatives." The bulk of the output is sold to refiners. The difference between production and sales—63,066,468 gallons—represents in part additions to stock, in part consumption as fuel, and in part crude tar treated on the premises in associated refining plants.

Ammonia recoveries in 1918 were reported partly as ammonium sulphate, partly as anhydrous ammonia. The total production in all forms amounted to 174,327,000 pounds expressed as anhydrous ammonia. The total output expressed in terms of ammonium sulphate amounted to 697,308,000 pounds. The exact quantity recovered in each form is not certain. Each producer was asked to state (1) pounds of ammonium sulphate produced; (2) gallons of ammoniacal liquor produced, giving average strength in per cent NH_3; (3) pounds of anhydrous or free ammonia produced, including the liquor and sulphate sold on pound basis of NH_3. In reply to the first of these questions a total of 436,388,134 pounds was reported, indicating that the production of sulphate as such amounted to at least that figure. No liquor was reported as such in reply to inquiry 2, but the total of

65,230,159 pounds NH_3 given in answer to the third inquiry probably included the equivalent of a certain quantity of liquor, and also of ammonium sulphate; how much of each is unknown. The returns may be summarized in the statement that at least 63 per cent and possibly more of the output in 1918 was recovered in the form of sulphate.

Practically all the ammonia produced was sold, the small difference being largely attributable to additions to stock after the break in price, which occurred a little before the signing of the armistice. The total value of the ammonia sold, in all forms, was $26,442,951.

Equal in importance to the ammonia compounds as a source of auxiliary revenue was the group of benzol products. The washing of coke-oven gas to recover the "benzols" on a significant scale in the United States dates back to 1915, when the Allied war orders for munitions began to flow into this country. At that time comparatively few by-product plants were equipped with stills to refine their own crude light oil. By 1918, however, it had become the general practice to conduct at least the preliminary stage of refining on the premises. The production of crudes in 1918, including oil later refined, was 87,222,450 gallons of crude light oil and 339,644 gallons of secondary light oil, a total of 87, 562,094 gallons. Of this quantity 3,885,463 gallons (crude and secondary), or about 4 per cent of the production, was sold. The remaining 96 per cent was treated on the premises, yielding 44,804,900 gallons of benzol (crude and pure), 8,861,948 gallons of toluol (crude and pure), 3,540,162 gallons of solvent naphtha, and 636,707 gallons of xylol and other valuable oils. The residue unaccounted for by sales of crudes or recoveries of refined products amounts to about 6,400,000 gallons, or 7 per cent of the crudes produced. This is understood to represent in part naphthalene, in part additions to stocks, and in part unsalable products which are used about the plant or returned to the gas. Of the benzol and toluol produced practically all was sold, although as a result of the collapse of prices after the armistice was declared there were slight additions to stocks. Sales of solvent naphtha and other oils amounted to 89 per cent of the production.

The total revenue derived from the group of benzol products was $25,700,000, of which nearly half was contributed by toluol alone. The average price realized for all the toluol sold was $1.43 a gallon. Next to toluol in point of value came benzol itself, with total sales amounting to $11,966,000, an average of $0.28 a gallon. The naphthalene recovered in 1918 amounted to 16,088,000 pounds. Practically all of this was sold, much of it for the manufacture of moth balls. The proceeds of the sales were reported at $650,000. Two-thirds of the quantity sold was in the form of crude naphthalene, defined as having a solidifying point below 79° at an average value of 2.8 cents a pound. The refined naphthalene, solidifying at over 79°, sold on the average for 6.6 cents a pound, more than twice as much. Other minor products to the aggregate value of $1,756,000 were sold.

Second in value among the by-products to the ammonia group and the benzol group ranked surplus gas, of which sales amounting to $13,700,000 were reported in 1918.

Disposition of the gas generated at by-product coke plants in 1918.

	M cubic feet.	Per cent.
Wasted	15,800,363	4.1
Burned in coking process	210,876,312	54.8
Surplus sold or used:		
For illuminating and household use	33,437,991	8.7
For industrial purposes	124,920,488	32.4
	385,035,154	100.0

The surplus 158,358,479,000 cubic feet available for use in other departments about the plant or for delivery to outside consumers is to be properly regarded as sales and should be credited to the operation of the by-product coke plant.

A tendency of recent developments in the by-product coke industry has been the construction of plants with retort ovens designed primarily to supply gas for city use. It is thus significant that approximately 33,000,000,000 cubic feet of by-product oven gas was delivered for illuminating and domestic use in 1918, at a total value of over $7,000,000, an average of $0.21 a thousand feet. This represents not the price to the consumer, but the average price realized by the producer, excluding costs of distribution, etc. Although the quantity used for industrial purposes was nearly four times as great (124,920,000,000 cubic feet), the value placed upon it was slightly less than that of the illuminating and domestic gas, amounting to $6,569,000, or $0.053 a thousand. The low value per thousand feet reported for the industrial gas is explained by the fact that the great bulk of it is used in associated steel plants, to which it is supplied at nominal rates. The quantity of by-product gas used in 1918 in iron and steel manufacture is not known accurately, but it is probably about 120,450,000 M cubic feet.

Sales of all by-products in 1918 amounted to $74,602,000, or $2.87 for every ton of coke produced. This was far from being a net rebate on the costs of each ton of coke, however, for it represents gross revenue only, out of which must come all the expenses of by-product recovery. The gross contribution from each by-product was as follows, ranged in order of rank:

Receipts from sales of by-products per ton of coke produced, 1918.

Ammonia	$1.02
Benzol group	.99
Gas	.53
Tar	.24
Miscellaneous products	.09
Total by-products	2.87

These figures represent war-time prices, it must be remembered, which, especially for the benzol group, were much above normal. Under those prices ammonia leads as the most important by-product, assuming again a place which it had lost to the benzol products during 1916 and 1917.

RELATION OF BY-PRODUCT COKE INDUSTRY TO THE ARTIFICIAL-GAS INDUSTRY.

The gas and other by-products obtained in by-product coking operations can be intelligently understood only if viewed in conjunction with the other sources of gas and of coal by-products.

Artificial gas is produced in the United States by a group of closely related industries. In addition to the surplus gas produced in the manufacture of by-product coke, which is available for domestic and industrial use, there are municipal gas plants that supply either coal gas, water gas, or oil gas, or a combination of two of them. These four kinds of gas have been treated in the statistics published by the Geological Survey as a common supply available to consumers of gas fuel. In addition, large quantities of producer gas and blast-furnace gas are produced annually, but as they are seldom sold outside the plants in which they are produced, no statistics concerning them have been collected.

The following table summarizes the consumption of artificial gas in recent years. For each item the measure of consumption is taken to be the quantity sold rather than the quantity produced.

Artificial gas consumed in the United States 1915–1918, by kinds.

	Quantity (M cubic feet).	Value.	Average value per M cubic feet.
1915.			
Coal gas	43,747,432	$40,257,108	$0.92

Oil gas and water gas	168,196,826	145,346,976	.86
1918.			
Coal gas	42,659,487	42,846,964	1.00
By-product gas	158,358,479	13,699,515	.09
Oil gas and water gas	192,281,580	171,154,159	.90

The surplus gas of by-product coke ovens has thus become a material factor in the supply of gas fuel. In terms of cubic feet it amounted in 1918 to nearly four times as much as the coal gas sold and came within 16 per cent of the oil and water gas. Moreover, it is increasing in output more rapidly than either of the others. The sales of coal gas decreased slightly from 1915 to 1918, and those of oil and water gas increased only 37 per cent, but the sales of surplus coke-oven gas nearly doubled.

In the following table are given the sales of the principal by-products reported by the group of artificial-gas industries in 1918. For some products—for example, the naphthalene, ammonia, and retort carbon recovered from coal gas and by-product coke-oven gas—the sales are practically identical with the production. But for other by-products the sales may be much smaller than the output, because part of the output is used about the works. Thus tar, particularly water-gas tar, is often used as boiler fuel. Coal-gas tar is sometimes treated at the works for recovery of coal-tar derivatives. The carbon residue or lampblack obtained in the manufacture of oil gas may be used as boiler fuel at the plant or briquetted and sold as domestic fuel.

For all these products the statistics of sales are of value because they give a measure of the surplus of each material placed on the market and therefore available for use by other industries. In the case of one group of by-products, however, the light oils or "benzol products," the figures of sales mean little except when studied in conjunction with statistics of production. As the source of benzol and toluol, the bases of the most important high explosives, the light oils received great attention during the war. Stripping plants to recover the light oils from the gas were erected at practically all by-product coke plants and at many municipal gas plants, and the production was greatly increased.

Light oil and other crudes produced in 1918, in gallons.

Crude light oil:	
By-product ovens	87,222,000
Water gas	15,924,000
Coal gas	5,914,000
Secondary light oil:	
By-product coke ovens	340,000
Water gas	9,000
Drip and holder oils:	
Water gas	3,365,000
Coal gas	117,000

The process of refining the crudes to recover benzol, toluol, and other fractions is sometimes conducted at the coke oven or gas plant and sometimes at central refining plants to which the crudes are shipped for treatment. The total production of pure benzol in 1918, from all sources, including petroleum oils, has been estimated at 44,000,000 gallons, and the production of pure toluol at about 14,000,000 gallons.

By-products of gas manufacture marketed in the United States in 1918.[a]

Product.	Quantity.	Value.
Tar (gallons):		
Coal gas	47,727,839	$1,863,580
Water gas	54,733,478	1,789,898
Oil gas	550,006	15,967
By-product	200,233,002	6,364,972
	303,244,325	10,034,417
Ammonium sulphate or equivalent (pounds):		
Coal gas	53,900,464	1,453,070
By-product	697,308,770	26,442,951
	754,209,234	27,896,021
Light oils (gallons): [b]		
Coal gas and water gas	12,347,288	6,992,987
Oil gas	20,376	4,274
By-product	59,564,376	25,688,446
	71,932,040	32,685,707
Naphthalene (pounds):		
Coal gas and water gas	896,080	14,282
By-product	15,890,447	650,229
	16,786,527	664,511
Retort carbon (short tons):		
Coal gas	1,007	13,275
Water gas	251	2,230
By-product	655	2,732
	1,913	18,237
Lampblack and carbon residue (short tons): [c]		
Oil gas	17,678	95,211

[a] Other products not included in this table, valued at $1,808,515 in 1918, were, from coal-gas plants, creosote, tar distillery products, pitch, coke breeze, and spent oxide; from oil-gas plants, yellow prussiate of soda; from by-product coke oven plants, coke breeze, sodium ferrocyanide, residue, drip oil, spent oxide, and pyridin oil.

[b] Including crude light oil, secondary light oil, benzol, toluol, solvent naphtha, and drip oils.

[c] Exclusive of briquets made from carbon residue.

REFERENCES TO THE COKE INDUSTRY CONTAINED IN THE REPORT OF THE DISTRIBUTION DIVISION OF THE U. S. FUEL ADMINISTRATION.

In the report of the distribution division of the United States Fuel Administration is to be found much information concerning the coke industry during the war period, particularly on the subjects of requirements and consumption. The report is published in three parts as follows: I, The distribution of coal and coke, by C. E. Lesher; II, The zone system, by Wayne P. Ellis; III, Statistical tables, by C. E. Lesher. Any part may be had upon application to the Director, United States Geological Survey. Appended is a list of references concerning coke contained in these reports.

Barytes and barium products, production, by States 951–952
stocks at mines 952
Basalt and related rocks (*see also* Stone) .. 1230–1234
general statistics 1230–1233
paving blocks 1231
prices 1231–1332
value, by States 1202, 1230, 1231, 1233
by uses 1230–1232
war uses 1234
Basic slag, imports 204
Beach, L. M., paper on feldspar 945–949
Bedford oolitic limestone 1262–1267
minor products 1267
prices 1265
production 1262–1266
shipments 1266–1267
Belgian Kongo, cement 587
graphite 263
Belgium, barytes 959
cement 592–593
coal, exports to 1358
flint pebbles, imports 1186
marble 1245
phosphate rock 203, 216
exports to 206
Belleek ware 896, 899
Bermuda, cement, exports to 587
coal, exports to 1358
coke, exports 1513
lime, exports to 850
mica, exports to 651
phosphate rock, exports to 206
salt, exports to 124
stone, exports to 1208
Birmingham, Ala., coke, prices 114–115
Bittern, potash salts, from 405
Bituminous rock. (*See* Asphalt and bituminous rock.)
Blast-furnace dust, potash from 406–407
Bluestone, production, by States (*see also* Stone) 1297–1298
by uses 1298
Bolivia, asphalt 463
barytes 959
cement, exports to 587, 593
coal, exports to 1359
lime, exports to 850
Bone china, delft, and belleek ware, production 896, 899
Bone dust, imports 204
Borax. (*See* Sodium salts.)
Borneo, petroleum 1169
Bort, imported 11
Bowling Green limestone 1269–1270
Brazil, asphalt 463
cement, exports to 587, 594
coal, exports to 1359
coke, exports to 1513
graphite 228, 244–245
gypsum, exports to 292
lime, exports to 850
mica 635–636, 650–651, 667, 675–676
petroleum, exports to 1133–1134
salt, sources of 127
sand and gravel, exports to 309
stone, exports to 1208
sulphur, exports to 365
Brick clay, production, by States 911, 914
Brick, common 869, 879, 884
Brick and tile 866, 875–892
architectural terra cotta 869, 880, 887
common 869, 879, 884
Hudson River district 889–892
drain tile 869, 880, 886
enameled brick 869, 880
exports 905
face, quantity and value 869, 880, 886
fancy or ornamental, value 869, 880
fire, quantity and value 869, 882, 888
fireproofing and hollow building tile. 869, 881, 887
imports 904
prices, by States and kinds 870, 879–882
production, by States 866, 875–888
quantity and value 866–867, 869, 879–882
Page.
Brick and tile, rank of producing States ... 879–882
sewer pipe 869, 880, 886
stove lining 869, 881, 887
tile, not drain 869, 881, 887, 888–889
vitrified paving, quantity and value 869, 879, 885
British Africa, asphalt 463
barytes 959
asbestos, imports from 553
cement, exports 587
coal, exports to 1359
gypsum, exports to 292
magnesite 156
mica 650–651, 668, 684
natural soda 179
petroleum, exports to 1133–1134
potash, imported from 395
salt, exports to 124
stone, exports to 1208
sulphur, exports to 365
talc 561–562
British Australasia, petroleum exports to. 1133–1134
British East Indies, asphalt 463
cement, exports to 587
graphite 257
gypsum, exports to 292
pebbles 1186
petroleum 1143, 1145, 1166
exports to 1133–1134
imports from 1129
potash, imports from 395
soapstone 561
British Guiana, asphalt 463
cement, exports to 587, 594–595
coal, exports to 1359
lime, exports to 850
mica, exports to 651
petroleum 1157
salt, exports to 125
slate, exports 279
British Honduras, cement, exports to 587
coal, exports to 1358
lime, exports to 850
mica, exports to 651
salt, exports to 124
British India, asphalt 463
cement 587, 595–596
flint pebbles, imports 1186
ozokerite, imports from 1129
paraffin wax, imports from 1120
petroleum 1133–1134, 1143, 1145, 1166
potash, imports from 395
salt, exports to 124
stone, exports to 1208
imports from 1212
British Isles. (*See* Great Britain.)
British Nyessaland, mica 635–636, 668, 683
British Oceania, asphalt 463
cement 587
coal, exports to 1359
lime, exports to 850
petroleum 1143
exports to 1133–1134
phosphate rock, exports to 206
British West Indies, asphalt 458, 463
cement, exports to 587
coal, exports to 1358
lime, exports to 850
mica, exports to 651
petroleum, imports from 1129
salt, exports to 124
imports from 123
slate, exports to 279
stone, exports to 1208
Bromine, by R. W. Stone (*see also* Salt, bromine, and calcium chloride). 131–133
Building operations, by cities 926–944
Building sand, production 305–306, 312
Building stone. (*See* Stone.)
Bunker coal trade 1362, 1365
Burchard, Ernest F., paper on cement 565–627
flourspar and cryolite 317–329
Burrstones and millstones, imports 1174
By-products from manufacture coke 1517–1523

coke breeze 1514–1517
coke ovens in the United States 1450, 1474, 1480–1491
beehive coke ovens, 1917–1918 ..... 1449–1450, 1483
completed and under construction, 1880–1918, diagram 1481, 1483

Page.

Coke, by-product coke ovens, 1917–1918 ... 1450, 1483
coke ovens, capacity of 1485–1487
completed and under construction, 1893–1918, diagram 1482, 1483
under construction 1483, 1485, 1491
list of by-product coke plants. 1487–1491
coke-producing industries 1445–1447
beehive coke 1445–1447
by-product coke 1445–1447
gas-house coke 1445
petroleum coke 1445
Connellsville, Pa., district, 1880–1918. 1476–1477
operating conditions, by weeks 1455
prices 1497–1498
consumption 1494–1495
domestic coke 1494–1495
foundry coke 1494–1495
furnace coke 1494–1495
distribution of coke 1507–1514
beehive coke shipped by originating railroads and waterways, by States, 1917–1918 1507–1511
shipments of Connellsville coke, 1914–1918, by months 1477
diagram showing production of pig iron and beehive coke, by months, 1915–1918 1443
diagram showing percentage produced and percentage lost 1442
foreign trade in coke 1511–1514
exports 1512–1514
by countries 1513
imports 1513–1514
prices, average at ovens 112–115, 1474, 1476–1480, 1496–1497
in Birmingham district 67–87, 114–115
by States 1497
in Connellsville region 113, 1497–1498
introduction 1439
production 1448–1480
beehive and by-product coke, 1917–1918 1449–1450
increase or decrease, 1918 1451
statistics of manufacture, 1880–1918 1474
yield of coke from coal, by States. 1450, 1474
beehive coke produced by months ... 1453
by States, 1909–1918 ..... 1450, 1452, 1474
by States and weeks, 1917 1477
in Pennsylvania 1477
West Virginia 1479
by-product coke, by weeks 1918–1919 1444, 1459–1473
by months 1458
factors limiting production 1458
in Ohio 1480
Pennsylvania 1478
West Virginia 1479
summary 1448–1451, 1456
total, 1880–1918 ..... In pocket.
rank of coke-producing States 1475
references to coke industry contained in report U. S. Fuel Administration 1526–1528
review of coke industry 1439–1445
curve showing beehive and by-product coke and pig iron produced in the United States, 1880–1918 1441
schedules used in canvass 1524–1525
unit of measurement 1439
values at ovens, of coke produced 1450, 1474
per net ton, 1880–1918 1474
change in schedules 1492
general statistics 1492–1497
prices, average, per ton 1496–1497
in Connellsville region 1497–1498
yield of coke from coal 1505–1506
Colombia, asbestos, imports from 553
asphalt 458, 463
cement, exports to 587, 596
coal, exports to 1358
mica 651
paraffin, imports from 1129
petroleum 1129, 1154
salt, exports to 124
sources of 128
stone, exports to 1208

[a] From 1871 to 1888, inclusive, production reported in this column is due principally to colliery consumption, which in some years was estimated and not included in the distribution by States. Since 1888 small, irregular production from several unimportant sources has been included in this column.

[b] Included under "Miscellaneous."

Division of Mineral Resources.

Compiled by Miss LIDA MANN, Statistical Clerk, under direction of C. E. LESHER.
